This picture of functional segregation was consistent with findings in human patients who had localized brain damage; for instance, such damage can abolish color discrimination with little effect on other aspects of visual perception. Since the 1990s, new methods of functional brain imaging have made it possible to explore localization of function in the normal human brain (*see* Functional Brain Imaging of Language processes). These have confirmed that visual stimuli activate multiple brain areas, each responding to particular stimulus properties. The activation of a particular area also depends on the visual task the subject is set and whether they are attending to the stimulus, showing that vision cannot be thought of as a purely 'bottom-up' or 'feed-forward' neural process, in which information originating in the receptors is progressively transformed. Rather, the results of high-level processes can modulate how low-level processes operate. An anatomical basis for this is provided by 'descending' connections from higher to lower visual areas, which are at least as rich and complex as those transmitting information from lower to higher processing (Bullier, 2004).

These concepts of neural information processing inform current research on all aspects of vision. In this article they are illustrated primarily with respect to the representation of pattern, shape, and spatial layout. They also underlie current understanding of other perceptual functions such as motion, color, and depth perception.

Representation of Spatial Pattern and Shape

Receptive Field Structure and Specificity

The richness of vision as a source of information comes largely through the detailed pattern of light and dark that arises from the spatial structure of the environment. Encoding of this pattern begins in the retina. The receptive fields of retinal bipolar and ganglion cells have a center–surround opponent organization. In an 'on-center' cell, light in the receptive-field center activates the cell, but this is countered by inhibition from light in the surround. Off-center cells show the opposite relationship. In either case, the activity of the cell signals the presence of spatial contrast between center and surround, with little or no response to a uniform field of light covering the whole receptive field.

The signals in the optic nerve therefore highlight the field locations where spatial structure is present, but carry little explicit information about the nature of this structure. Ganglion cell receptive fields are circular, and so respond equally to the contrast in an edge crossing the field whether this edge is horizontal, vertical, or oblique. Neurons in area V1 also respond to local contrast, but mostly have receptive fields with a particular preferred orientation, as discussed in the Section Receptive Fields and Tuned Filters. Neurons with different preferred orientations ensure that contours at any angle around the clock are represented by activity within V1. Orientation seems to be a key organizing principle for V1, demonstrated by the way neurons are laid out in a semiregular array of 'orientation stripes' across the cortical surface; presumably this provides the initial basis for the neural representation of shapes and textures.

A second important organizing principle is that of multiscale representation. Some cortical neurons respond to very fine-scale spatial detail; others, covering the same region of space with larger receptive fields, respond to similar features on a much coarser scale (De Valois and De Valois, 1988). Mathematically, this variation of scale corresponds to different neural channels responding to different spatial frequencies within a region of the image. Computational studies show that this local analysis in terms of component spatial frequencies is an efficient way to capture the significant structure of scenes, as outlined in the next section.

From Measurements to Spatial Primitives

The multiscale array of orientation-selective neurons in V1 can be considered as making a comprehensive set of measurements of the image. To develop a useful representation of scenes and objects, these measurements need to define primitives – elements of an 'alphabet' of spatial structure through which more complex entities can be represented. Thus, a measurement of contrast in a particular orientation and scale does not itself unambiguously define an edge segment; but in conjunction with nearby measurements at a range of scales, it can provide the basis for an assertion of a local edge-segment primitive (Frisby and Stone, 2010: ch. 5). While such primitives are important in the computational description of what the visual system is doing, it is unclear whether neurons in visual cortex explicitly represent primitives, or rather whether these are implicit in the pattern of connections amongst V1 cells and from V1 to higher levels. In any case, the separation of information into different spatial frequency bands (scales) appears to be a characteristic of the neural organization at the level of V1 but is not a feature of the higher levels of the processing hierarchy.

Grouping Processes and Figure/Ground

To yield descriptions of object shapes and bounded surfaces, local edge primitives must be grouped together to form extended contours and areas with a common texture. The importance of grouping phenomena was first recognized by the Gestalt psychologists in the early twentieth century, who

argued that perception could not be understood in terms simply of the response to local elements but that 'the whole is greater than the sum of its parts.' A plausible neural basis for some aspects of grouping exists in the horizontal connections between V1 cells tuned to a similar orientation. Contours, in turn, define the boundaries of surfaces and objects. In particular, such boundaries establish the key perceptual distinction between the 'figure' to which the contour belongs and defines its shape, and the 'ground' or background; the contour marks the point where the ground is concealed by the object, but indicates nothing about the properties of the ground itself. If there are markings on the background, these are interrupted by the occluding contour. This interruption by occlusion can give the perception of an edge, even if there is no difference in overall luminance level of the figure and the ground – an effect sometimes called an 'illusory contour.' Peterhans and Von der Heydt (1991) have found neurons in V2 which respond to the characteristic configuration of contour elements where one surface occludes a background surface. Such neurons respond to an illusory contour or a contrast edge at the same preferred orientation, and so represent the boundary of an object in an invariant way, whether it is indicated by a difference in light intensity or by the interruption of background markings. The activity of neurons in V1 and V2 also reflects the figure/ground distinction; the response of a neuron that prefers an edge, which is dark on the left and which may be modulated by whether the left-hand region belongs to an occluding figure or the occluded background. The timing of this modulation suggests that it is the result of feedback from higher visual areas that extract figure-ground relations from the image – an example of the role played by recurrent loops in computing information about the world from information in the image.

Recognition

One important end-point of the processing of spatial pattern is the visual recognition of objects, faces, and scenes. Damage to the temporal lobe of the brain can specifically impair object recognition (agnosia), sometimes limited to a particular class of objects, notably a lost ability to recognize faces (*see* Prosopagnosia). Functional imaging studies show a network of areas that is selectively activated during the processing of faces (in particular, the fusiform face area on the lower surface of the temporal lobe) (*see* Face Recognition, Psychological and Neural Aspects), and another that is active in visual recognition of locations (the parahippocampal place area). Recordings from individual neurons are not generally possible in humans, but in the temporal lobe of the monkey, Gross, Rolls, and others found single neurons that respond specifically to faces. The pattern of activation over a small number of such cells can convey sufficient information to distinguish one individual from another. The inferotemporal region of the monkey brain contains cells that respond to features that can define different types of object. In both face- and object-selective neurons, the neuron's response shows position generalization; that is, it is selective for a particular class of stimulus, irrespective of its position within a wide receptive field.

Thus, the principles of a sparse population code, found in the representation of local pattern in V1, appear to apply also to the higher-level representation of visual identity (reviewed by Thorpe in Kriegeskorte and Kreiman, 2011; see also Barlow, 1995)). There must be a series of neural transformations that assemble information about local pattern features, to identify the characteristics that define a particular object category. Investigations of neurons along the ventral processing stream (see below) are beginning to reveal some of the two- and three-dimensional elements which are used to define perceived shape – for example, neurons which encode the location of sharply curved points around an object's contour (reviewed by Kourtzi and Connor, 2011). However, the hierarchy of neural transformations that connects the representation of shape elements with the identification of objects is still not well understood.

Spatial Location and Layout

As well as allowing the identification of objects and scenes, vision defines the space within which objects are located and are the targets of actions. Disturbances of spatial abilities are found with damage to the parietal lobe in both human and monkey brains (Ungerleider and Pasternak, 2004). These disturbances are quite distinct from the impairment of object recognition seen from temporal lobe damage, leading to the proposal of a broad division between a *ventral stream* of cortical visual processing, from V1 to temporal lobe and concerned with identifying what we are looking at, versus a *dorsal stream* from V1 to parietal lobe which conveys the information needed to know where it is and how we can act upon it. Different specialized visual areas contribute to the two streams; in particular, the motion area V5 (MT) sends information primarily via the dorsal stream (*see* Visual Streams: Dorsal and Ventral).

Spatial information requires a frame of reference. Area V1, and other early visual cortical areas, appear to be organized within a retinotopic frame – that is, the receptive fields, and their topographic arrangement across the cortex, are defined in terms of image locations on the retina. As the eyes are constantly moving in the head, a stable representation of space requires more than retinotopic information. Eye direction must also be factored in, to establish a head-centered frame. Such combination of retinal and eye-direction information occurs in a number of parietal areas. However, the properties of cells in different parts of parietal cortex suggest that they are preparing visual information in an appropriate form for controlling different action systems – for example, eye movements, reaching and grasping by the hands, and locomotion. Parietal neurons appear to be quite flexible in the use of eye-, head-, and body-centered frames, although it has been suggested that the retinotopic frame may serve to communicate between different action systems. An alternative frame of reference is allocentric, that is, referred to the layout of the environment rather than any part of the body of the observer. It has been suggested that this is a feature of the ventral stream, which has to identify objects independently of any particular viewpoint.

Parietal areas transmit information to motor-related areas of the frontal lobe, both directly and via the cerebellum. Comparison of cells in the parietal lobe with those in the

premotor frontal areas to which they project emphasizes how difficult it is to define any boundary between visual and motor processing. For instance, activity in some parietal neurons is associated both with viewing a particular three-dimensional shape (e.g., cylinder) and with the grasping action required by that particular shape. 'Mirror neurons' in premotor cortex respond both in association with the hand action of the monkey, and when the monkey is passively viewing another hand executing the same action. The linked parietal and frontal systems are best thought of as a set of visuomotor circuits which embody the spatial information needed to control and define a particular type of action, converted between reference frames as necessary.

The Binding Problem

Research on visual neuroscience has emphasized the fragmentation of brain processing. Any visual stimulus will activate many different neurons. Distinct brain areas and subsets of neurons process different attributes such as shape, color, and motion, and there are multiple spatial representations in different visuomotor circuits. In contrast, our experience of the visual world appears unified, and the different attributes of a visual object are bound together – if a white cup and a green book are together on the table, we do not confuse which color belongs to which object. How this perceptual unity arises from fragmented neural representations is known as the binding problem (Treisman, 1996).

Two, not necessarily incompatible, answers have been widely discussed. One is based on Anne Treisman's feature integration theory of attention. This theory, supported by evidence from visual search, proposes that a 'spotlight' of focal attention modulates processing within distinct 'feature maps' for different attributes (perhaps embodied in the multiple retinotopic areas of extrastriate cortex), and so multiple feature attributes are accessed only for the object that is the current focus of attention. The second idea is that cortical neurons show oscillations in their activity at frequencies around 40 Hz (the 'gamma-band'), and that temporal coherence between these oscillations acts as a label for different signals contributing to the representation to a common object. Such coding by temporal synchrony has attractions; it could provide a basis for understanding how features at different locations within a single map can be linked or segregated in object-based representations, as well as how binding occurs across different maps. However, the evidence for it remains limited and controversial. Gamma-band activity in electroencephalographic (EEG) recordings of large cell ensembles shows intriguing variations with perceptual processing, but its functional role is not yet understood.

Neural Basis of Visual Sensitivity and Thresholds

Much detailed knowledge of vision comes from the analysis of psychophysical thresholds – measures of how sensitive the visual system is in making fine discriminations (reviewed by Braddick, 2010). If these data are to be integrated with knowledge from neurophysiology, the relation between psychophysical threshold and patterns of neural activity needs to be understood.

'Threshold' conveys the suggestion of a stimulus intensity below which no neural activity is elicited. However, in practice, sensory neurons are rarely completely silent, and their activity, even with a fixed stimulus, shows variability or 'noise.' Thus, the ability to detect weak stimuli is determined by the statistical problem of distinguishing a stimulus-driven change in activity from those due to random noise.

Several studies have determined the 'thresholds' of single neurons in monkey visual cortex, in terms of the stimulus level which achieves a statistically defined level of reliable response. These can be compared with behavioral performance in detection of a trained animal; in some cases behavioral and neural measures can be made simultaneously. The information carried by single neurons proves to be remarkably close to that implied by the behavioral responses. Remarkable, because the animal has the opportunity to pool the information from thousands of neurons, which would be expected to yield much more reliable information. The data can be reconciled by realizing that although large numbers of neurons may be involved, the random variations in their activity are correlated so the number of genuinely independent neural signals is much smaller (Newsome et al., 1995).

Whether a particular judgment depends on pooling activity in tens, hundreds, or thousands of neurons, there must be many more neurons in the same brain area whose activity is irrelevant because they do not respond selectively to the stimulus concerned. If activity of such neurons was included in the pooling process, it would introduce noise and degrade sensitivity. Thus sensitive discrimination, either in the laboratory or in real-life situations, must depend on selecting a small minority of neurons whose output is informative for the task in hand – likely one of the skills that is acquired in perceptual learning.

Modulation of Neural Activity by Attention and Task Demands

It could be conceived that neural activity, relevant to a particular task, was channeled to appropriate decision and response mechanisms through a purely 'bottom-up' process. However, the Section Representation of Spatial Pattern and Shape has mentioned the ample evidence for 'top-down' control of visual processing, modulating activity at many levels according to the central decisions about what is relevant. For instance: (1) neural activity, as early in the pathway as the LGN, is strongly modulated according to the sleeping–waking state of the organism; (2) the response of single neurons in areas such as V4 and V5 in monkeys can be changed radically according to whether the preferred stimulus of the neuron is behaviorally relevant or irrelevant on a particular occasion; (3) functional brain imaging shows that the overall activation of an area such as V5 in humans is enhanced by attention to the property that it analyses (in this case, motion), even if the stimulus is unchanged; and (4) within a topographically organized area such as V1, activation of a particular region is enhanced when attention is directed to the corresponding region of visual space (*see*

Attention, Neural Basis of). Thus the neural mechanisms of visual perception work in a flexible way, directed by the processes of attention and executive function to be adaptive for the current goals of behavior.

Development and Plasticity of Visual Neural Organization

The organization described in the preceding sections is the product of a developmental process. The vision of the newborn baby has low acuity, in part because the foveal cone receptors are very immature and loosely packed, but also because most of the connections between neurons in the brain are not yet established. Over the first few months of life, V1 becomes functional as the characteristic tuning of the V1 neurons starts to develop, first for orientation followed by motion and then stereoscopic depth (Atkinson, 2000; Braddick and Atkinson, 2011) This is followed by the development of integrative processing in extrastriate cortical areas (Braddick and Atkinson, 2011). The dorsal and ventral cortical streams do not develop in step; global integration of motion in the dorsal stream emerges before corresponding processes for static form in the ventral stream, but this is followed by radical reorganization of brain networks, in which the dorsal stream appears to be particularly vulnerable in a range of developmental disorders, ranging from Williams Syndrome and autism to very premature birth and congenital cataract.

This vulnerability is an example of the plasticity of the visual system in development, which includes long-term adaptive changes, in response to the visual inputs received by the system. For instance, if the input to visual cortex has an anomalous distribution across the retina (e.g., as a result of a congenital absence of cones in the central fovea) the usual retinotopic map in V1 is distorted to match this distribution. When the balance of input from the two eyes is disturbed (e.g., when the input of one eye is reduced in a critical period during early development) the cortex adjusts to receive less input from the less active eye. The plasticity seen in these abnormal cases must also play a role in normal development: development of the normal neural organization of visual brain areas must depend on the regularities and correlations in the visual input that these areas receive.

Perceptual Learning

The Sections Modulation of Neural Activity by Attention and Task Demands and Development and Plasticity of Visual Neural Organization indicate ways in which the function of the visual system can be dynamically modulated, both from moment to moment and more permanently. This is also shown in the strong learning effects found for visual abilities; almost any visual discrimination becomes strikingly more sensitive with practice. This learning can be highly specific, for example, showing improvement for detecting stimuli only at the orientation that has been practiced, suggesting that changes occur at relatively low levels of visual processing such as V1. The discussion in the Section Neural Basis of Visual Sensitivity and Thresholds suggests that such learning may be based on establishing highly specific connections to decision mechanisms from the neurons most sensitive to the stimulus concerned. However, while changes with learning have been demonstrated in the responses of visual cortical neurons, the relation of these changes to modified neuronal connections is still speculative.

The Neural Basis of Visual Awareness

The detailed understanding of how visual information is represented in the nervous system does not answer the question: what aspect of neural activity corresponds to the conscious awareness of the observer? Many aspects of vision are not accessible to consciousness, even though the relevant information exists within the nervous system. For example, we cannot consciously tell whether a stimulus was delivered to the left or right eye, even though the two eyes activate distinct neurons in V1 and the distinction is critical for stereoscopic depth perception. This raises the question of whether there is any subset of visual neurons whose activity contributes specifically to awareness, constituting the so-called Neural Correlate of Consciousness (*see* Consciousness, Neural Basis of).

Individuals with damage to V1 report that they are blind in the region of the visual field corresponding to the damage. However, they can sometimes make reliable responses to stimuli they do not report seeing, a phenomenon named 'blindsight' by Weiskrantz and Warrington who discovered it in the 1970s. Thus there must be routes for visual information which can control behavior but whose activity has no conscious correlate – a pathway is known from the superior colliculus in the midbrain, bypassing V1 en route to the motion-sensitive area V5, which could provide such a possible route. However, it is not known whether V1 activity is itself a necessary correlate of conscious visual experience, or whether V1 simply serves as the only access route to higher processes that have such a correlate; there are difficulties with either alternative.

In binocular rivalry, discrepant patterns are presented to the two eyes, and alternate in conscious perception. Neuronal activity can be monitored in monkeys who are trained to indicate which pattern is perceptually dominant. For some cortical neurons, activity fluctuates in correspondence with perceptual dominance, but for others there is no correlation. The proportion in the former group increases in going from lower to higher cortical areas (Logothetis, 1998). These results suggest that awareness is not uniquely associated with particular cortical areas, but may emerge cumulatively as information is processed through the system. The true relation between brain and consciousness will remain speculative for many years, but visual processing is likely to provide the key test cases for this central problem of the human sciences (*see* Consciousness, Neural Basis of).

Abstract

Visual sociology is a new and rapidly expanding field of sociological research and theory. It is considered as either (1) a new subdiscipline of sociology concerned with the iconosphere and the visual sociosphere of contemporary society or (2) as a methodological orientation supplementing standard methods of qualitative research, applicable to all substantive areas of sociology. The emergence of visual sociology reflects an important shift in the culture of modern society, from written texts to images. Both the purposefully created pictures and the visible, outer layer of social behavior are rich and dense. Interpersonal communication is also pervaded with images. We live in the exhibitionist and voyeuristic society, and this is manifested in six ways: as the society of the icons, of the spectacle, of the self-presentation, of the design, of the surveillance, and of gazing. Visual sociology explores these new features and uses the cognitive opportunities they provide. As a young direction of inquiry, it grapples with some philosophical dilemmas: realism versus constructivism, and universalism versus relativism. Irrespective of these controversies, the main message of visual sociology is to look around and to develop visual imagination, that is, the skill of translating abstract concepts and theories of sociology into their observable manifestations in everyday life, and to interpret the iconosphere and visual sociosphere in terms of sociological concepts and theories.

The Visual in the Focus of Current Debates

The visual aspects of social life – that is, all that is accessible to sight as well as all social phenomena and processes related to seeing and being seen – have become one of the central concerns of the contemporary social sciences. Some scholars believe that this signals a new turn, similar to the linguistic turn in the philosophy of the 1970s: "visuality is emerging as a central topic of discussions in the human sciences in the way that language did …. The focus shifts from words to pictures, the sayable to the seeable" (Mitchell, 2006: 9, 10).

In 1994 two scholars, working independently, gave the emerging trend its labels. The Swiss art historian Gottfried Boehm coined the term 'iconic turn,' and the American literary critic W.J.T. Mitchell introduced the idea of the 'pictorial turn.' Boehm focused mainly on the changes at the intellectual level: a new approach to the visual domain departing from the traditions of the history of art. The main point is to go beyond the sphere of art and extend research to all sorts of visual representations, establishing the more comprehensive 'image science' (Boehm, 1994). This is justified by the fact that "pictures privileged by the descriptive label 'art' constitute only a small portion of the sea of imagery in which the world cultures are adrift" (Moxley, 2008: 136).

Mitchell, on the other hand, calls for the departure from the traditional perspective that treats pictures only as vehicles of meaning, as representations of other objects, toward recognizing that they have some independent status within culture, 'lives' and 'wishes' of their own, and that they 'want' something and 'say' something to us. As such they possess some agency, exerting influence on people and their behavior. Therefore they should be treated as valid objects of inquiry per se, and not only as indicators of some other objects such as meanings or structures (Mitchell, 1994). This idea was taken up later by the proponents of the so-called performative approach, Jeffrey Alexander and others (Alexander et al., 2006, 2012).

Both Boehm and Mitchell, but even more their followers, recognize that such changes at the intellectual level are not autonomous but reflect changes in the society of our time, in the period usually called late modernity, high modernity, or postmodernity (Giddens, 1990; Jay and Brennan, 1996). They join a number of scholars who perceive the shift in popular culture and everyday life toward pictures and away from texts. Some, more sociologically inclined, observe the proliferation of pictures as forms of communication and representation. Others, closer to psychology, claim that images and not only words become the means of human thinking. The emergence of the iconic language is supposed to signify the end of the 'Guttenberg Galaxy,' the rule of the printed word. As a famous photographer, Andreas Feininger, puts it: "In contrast to the printed page, a photograph can be 'read' at a glance – and people seem to get more and more restless, impatiently waiting to go on. The language of words – reading – is slow and generally losing its importance in favor of the language of the image – TV, pictorial advertising and photography" (Feininger, 2004: 4). Already at the end of the 1970s and the beginning of the 1980s, the work of Jean Baudrillard (1994), Roland Barthes (1983), and Susan Sontag (1978) emphasized this striking ontological feature of contemporary society, namely its saturation with pictures, images, the expanding iconosphere, as well as tremendous enrichment of the directly observable outer layers of social life, of the visible sociosphere. Modern, but particularly late modern capitalist, consumer society is particularly rich in visibility, saturated with pictures and icons, bristling with images, diversified and colorful visual impressions. And people are paying more attention to external, visible layers of social reality. We live in the exhibitionist and voyeuristic society. Sociologists could not remain insensitive to these changes. As Douglas Harper puts it, "making sociology visual was a parallel to making society visible" (Harper, 2012: 2, 3).

The Exhibitionist and Voyeuristic Society of Our Time

The growing importance of the visual domain is manifested at six levels of everyday life. First, we live in the *society of the icons*. We are surrounded with lots of intentionally created pictures: billboards, commercials, advertisements, banners, flags, coats of arms, color magazines, TV programs, the Internet, and multimedia presentations. Not only in tabloids, but in serious journals or even daily newspapers, photographs appear together with the written texts. Interestingly, the photo editors are also influenced by the Windows style, and instead of the full-page photos in the old days of *Life*, *Look*, *Paris Match*, and the *Illustrated London News*, we have large number of small images resembling another webpage on the Internet. The icons in all their variety are representations of something, but their main function is not to describe but to communicate some meanings, convey a message, 'make a statement' of some sort, and they have been created for that purpose. Their connotation is more important than their denotation.

Second, we live in the *society of the spectacle*. Many of the collective situations in which people find themselves are orchestrated according to some scenarios and occur in carefully designed settings. The rich visuality of social situations and social scenes is intended to impress, to convey directly visible, obvious meanings. In the domain of leisure, just think of the rock concerts where music no longer dominates and the lights, costumes, hairdos, choreography, fireworks, mists, and smokes are central elements of the performance. Or consider carnivals, celebrations of the New Year. In the area of sport, competitions turn to spectacles watched by millions of fans, as in the opening ceremonies of the Olympics, the World Cup in soccer, or the Rose Parade at Pasadena. In the area of the economy and consumption, just remind yourself of the shopping galleries or malls designed like baroque churches or royal palaces, shop windows arranged like theater stages or opera settings, Christmas markets, bank halls resembling museums, and executive offices with huge mahogany tables and carefully arranged family portraits. In the domain of politics, just look at the party conventions, presidential inaugurations, parliamentary rituals, patriotic parades, mass rallies, protest gatherings, and street riots. Even the domain of science has not escaped the tendency. Perhaps the most obvious case is that of Nobel Prize ceremonies, but the opening of each major international congress or academic conference is now accompanied by all kinds of ritual or even art performances. Science has also developed some characteristic formats of spectacles in which the debates are conducted or results presented: panel discussions, roundtables, and presidential addresses with large audiences. The educational, university context is also rich in spectacles. The commencements, parades of professors and students through town dressed in all these strange gowns and hats, and the honorary degree ceremonies, are rich in visuality and carried out according to strict scenarios. And it is hard today to attend a university lecture that does not use visual illustrations with the help of PowerPoint. Even the domain of death illustrates the trend. Funerals, particularly of public heroes or celebrities, turn into spectacles. No wonder that in most of such collective occasions we see hordes of press photographers. It is easier to grasp the meaning of these situations in pictures than in words.

Third, we live in the *society of the display*. The presentation of the individual, autonomous self, the universal human tendency so aptly demonstrated by Erving Goffman (1959), has found much more extensive and enriched manifestations. The syndrome of Thorstein Veblen's 'conspicuous consumption' (1994 [1889]), which in the old days was a way of life of the elites, *nouveau riches*, or celebrities, has become universal. The external, observable requisites – the cars we drive, houses we live in, dresses and shoes we wear, watches on our hands, jewelry on our necks, pens we write with, leather suitcases in which we carry office papers – are the symbols of status and building blocks with which we construct our identity, to be admired and envied by others. The celebrities whose lifestyles have become more accessible than ever through tabloids and snobbish magazines are serving as role models to be imitated. Famous brands have become democratized through franchising; they are much cheaper and more accessible than before. And for those who still cannot afford Rolex, Omega, Louis Vuitton, or Dolce y Gabana there are cheap fakes from Asia easily available in the street markets. In extreme cases, social identity is constructed exclusively on such grounds: there are communities of taste, of style, of trends and fashions, fans of sport cars, motorcycles, or boats, devotees of certain brands, demonstrating strong forms of solidarity formerly reserved to the believers in the same God or in the same Nation.

Fourth, we live in the *society of the design*. The attention devoted to the packaging, shape, and color of various products (just think of cars, boats, mobile phones, computers, skis, dresses, and ties); furniture of apartments; architecture of houses; and urban planning of streets, parks, stadiums, and airports is incomparable to any earlier era. The experts in design are everywhere and in great demand; it is their time. Everyday life of consumer society is saturated with tremendous diversity and variety of intentionally created visual impressions: of colors, forms, styles, and fashions. Consumers respond accordingly. We very often buy various products attracted by their design, and we often change still functionally efficient gadgets, TV sets, cars, computers, and cameras because of their new design, in order to catch up with novelty. This tendency is driven by the logic of the commercial competitive market, the need for novelty, originality, standing out, drawing attention, and even shocking the consumer.

Fifth, we live in *the society of surveillance*. The penetration of state coercive, regulatory, or administrative power to many corners of our lives occurs often by means of video surveillance: the hidden cameras in factories, stores, banks, hotels, offices, gas stations, streets and squares of the cities; and photo-controls of speeding on the roads. Criminal investigators use hidden video recordings as proofs at courts, arrange provocations in corruption cases, and so forth. We are amazed looking at Google Maps at how detailed the observations are that are provided by all those satellites flying invisibly over our heads. We are seen and observed by others without our awareness much more often than ever before. We are also made aware of social control and sanctioning of deviant behaviors by visible signs demonstrating binding rules, demanding certain behaviors or prohibiting others: traffic signs, and iconic signs at the airports, in railway stations, and on the streets.

Sixth, we live in the *society of gazing*. We avail ourselves of these new, immense opportunities of visual experiences, by intensifying our practices of observing, looking at others and the surroundings. The custom of Paris street cafes of leisurely looking at passersby has extended to many cities in the world. In the streets of any city – Rome and Paris, Amalfi and Florence, New York and Shanghai – what the people do most often is look at shop windows and take snapshots of everything. Taking the little digital cameras to their eyes has become the most frequent and common gesture of the human species. And returning home, we sit and look at TV, look at pictures on the Internet, glance through illustrated magazines, play computer games, and so on. A particular variety of this is gazing at movie stars, celebrities, or the 'rich and famous.' Crowds do it directly at film festivals, Oscar ceremonies, and the like; and readers of tabloids do it indirectly by looking at pictures of 'high society' with a mixture of awe and envy.

These new phenomena provide particular opportunities for sociological inquiry. All that we see around us, and not only what is to be found in pictures, may become the subject of study. Such inquiry may serve two purposes. First, it extends the field of research, the category of objects to be studied. We begin to treat pictures and observed images of social life as phenomena to be studied as intrinsically interesting parts of culture, the visual culture. They are the ultimate targets of research. But the iconosphere and visual sociosphere may also serve as means of research, as resources helpful in digging into the structures, mechanisms, and regularities of social life, a new research opportunity opening for social scientists due to the enhanced visuality of social life. Here the visual turn means adding a new approach (Prosser, 1998), a new orientation to those in the standard repertoire of the social sciences. In the discipline of sociology, the concern with visuality is marked by the birth and rapid development of the new area of research called visual sociology.

Emergence and Career of Visual Sociology

Sociology's concern with visuality is relatively new, and dates only to the last decades of the twentieth century. Among the classical authors, only Georg Simmel wrote about the observability of social interaction and its implications for sociological method in an essay published in 1908. He was particularly concerned with everyday life in the city, in the urban context, by its nature full of visual richness and diversity. He is also remembered for a striking remark that the eye is for a sociologist the most important of the senses (Simmel, 1921 [1908]: 358). But for the whole twentieth century the domination of techniques and procedures based on words and texts – surveys, questionnaires, interviews, content analysis, and more and more sophisticated statistical methods of interpretation – pushed visual data to the margin. It was only in the 1970s, when the so-called subjectivist turn toward symbolic interactionism, phenomenology, ethnomethodology, and so-called dramaturgical theory raised interest in the subjective data and qualitative methods, that the first large-scale photographic projects appeared in sociology. Their authors – Dough Harper, Bill Aron, Phyllis Ewen, Bruce Jackson, Mark Rosenberg, Edward Hall, and Erwin Zube – document the social life of various communities, with particular attention given to the more 'exotic' or deviant subcultures such as homeless people, vagabonds, hippies, or religious sects (Wagner, 1979; Collier and Collier, 1986; Harper, 2012). The year 1972 witnessed the birth of reflexive photography, known also as a collaborative visual method: Sol Worth and John Adair give simple cameras to some of the Navaho Indians and elicited spontaneous visual evidence of their way of life, systems of values and rules, and cherished objects as seen by the insiders (Worth and Adair, 1972; Collier and Collier, 1986). This approach has been used later on many other occasions.

The truly classical forerunner of visual sociology is Erving Goffman. He was the first to submit rich photographic material to a deep interpretational analysis aimed at unraveling hidden cultural premises and symbolic meanings. In his 1979 book, *Gender Advertisements*, he collected 508 photographs from the media, commercials, and private archives representing men and women separately and in various interactions in many contexts of everyday life. The expressive behavior captured in the pictures is, he believed, a good indicator of deeply hidden, often subconscious, culturally accepted standardized definitions of gender (1979: 7). According to these culturally imposed and internalized definitions, people present their selves to others on social stage. Being a man or a woman is expressed by self-presentations congruent with cultural images of masculinity or feminity.

But the founding event of visual sociology as a new, institutionalized discipline was the exhibition titled "Exploring Society Photographically" organized by a pioneer of the field, the well-known sociologist Howard Becker at Northwestern University in Evanston, Illinois in 1981 (Becker, 1981). Among 12 photographic projects included in the exhibition, most were of a clearly sociological character: the study of life in an Arkansas penitentiary, of migrant fruit pickers, of a community of elderly Jews; a look at the roller-skating culture of Venice, California, at patients in the hospital, at various work experiences, and the assimilation of American Indians. The exhibition catalog provided sociological interpretations of photographs as a method of unraveling hidden cultural and social patterns. In this way it set the standards for later similar efforts. Another milestone was a conference at Amsterdam in 1989 and the accompanying exhibition titled "Eyes Across the Water" (Flaes, 1989). Since that time, visual sociology has developed quite rapidly and acquired institutional and organizational forms. In the mid-1980s the International Visual Sociology Association was established. Specialized journals started to appear: in 1991 *Visual Sociology*, later renamed *Visual Studies*; *Journal of Visual Culture*; and others. A series of conferences followed, classes and seminars were opened at various universities, sections were created at some national sociological associations, and quite recently (2013) the Working Group on Visual Sociology was established within the International Sociological Association (ISA), well on the way to becoming a full-fledged ISA research committee.

There are several ways in which visual sociology is practiced. One tendency is treating visual sociology as one of the specialized subdisciplines with its own objects of study and research methods. There is a new 'tribe' of sociologists whose

self-defined identity is as visual sociologists (Nathanson and Zuev, 2013; Harper, 2012). But there is also the different approach in which visual sociology is considered as a general methodological orientation applicable in all specialized fields of sociological research. There is some parallel with other, rapidly developing areas of sociological interest: historical sociology or the sociology of knowledge (as distinct from the sociology of science). In spite of the misleading names, rather than narrow specializations, both are in fact wide theoretical and methodological orientations that can be applied in a number of – if not all – disciplines of sociology. The same is true of visual sociology. Treated in this way, it is only distinguished at the methodological level and not at the substantive level (Rose, 2001). It is relevant for many substantive areas, where the iconosphere, visual sociosphere, or visual practices are rich enough – perhaps most obviously for the sociology of everyday life and of interpersonal behavior; but also for urban sociology, sociology of work, sociology of religion, sociology of leisure, sociology of sports, sociology of social movements, and many other subdisciplines. In most of them the visual orientation comes down mainly to interpretational procedures (Sztompka, 2006/2012, 2012).

Those who consider visual sociology as a separate discipline still differ as to its proper objects of study. Some limit its target to the iconosphere, the purposefully created pictures communicating some meaning or carrying a certain message encountered in the environment of everyday life (Sztompka, 2008). Among them the central place is usually reserved for photography, but other types of visual representations are also included: video recordings, movies, TV pictures, computer presentations, and even murals, graffiti, tattoos, photo-blogs on the Internet, and so forth. The wider approach also includes the visual sociosphere, that is, not only purposefully produced pictures but the whole visual, observable layer of social life, reflected as images in the minds of the people. As Emmison and Smith declare: "Visual inquiry is no longer just the study of the image, but rather the study of the seen and observable" (2000: ix). The study of the iconosphere and visual sociosphere requires interpretation, the search for meaning, either what the pictures and observable manifestations of social life represent (denotation) or what they imply, suggest, and symbolize (connotation).

A somewhat exotic focus has become fashionable recently. It is no longer concerned with the iconosphere or visual sociosphere and its content, or meaning, but rather on social practices through which pictures, icons, or images are produced or perceived (imagined), distributed or shared, preserved or remembered. The proposed methods of research are congruent with this approach. The study of the visual practices of depicting and perceiving treats visual data as any other cultural component, and approaches visual data not from the internal perspective of meaning but from the external perspective of the cultural and social contexts or 'discourses' in which they appear, including even the material aspects of certain tangible objects (e.g., snapshots) that people handle and use in specific ways. It proposes looking 'behind the pictures' rather than 'at the pictures' or 'through the pictures' (Wright, 2008).

Current Debates

More deep and fundamental divisions within visual sociology have to do with philosophical assumptions, whether consciously adopted or only implied by the research modes. There are two frontiers of the battle: realism versus constructivism and universalism versus relativism. The early forerunners of visual sociology – Roland Barthes, Susan Sontag, Margaret Mead, Erving Goffman, as well as classical photographers Edward Weston, Laszlo Homoly-Nagy, August Sander, and Andreas Feininger – accepted a realist perspective: photographs represented something that really exists in front of the lens, the objective facts, phenomena, and events (Cartier-Bresson, 1952). For Sontag, photographs were the "miniatures of reality" (1978: 4). The photographic techniques (at least of the traditional analog form) assure that the visual, observable features of reality are reflected, imprinted on the light-sensitive paper. Photographs therefore constitute a proof, the strong evidence of something that happened. In the same vein, the sociological photographs capture and preserve the looks and behavior of the people, individually or collectively; the social events and occasions that actually occurred; social situations and civilizational environments as they really existed: "photography is the somehow natural witness of 'what has been'" (Wright, 2008: 17).

At the opposite pole to the realist perspective are various versions of constructivism (Berger, 1972). In the neo-Kantian mood they claim that the world does not exist per se, but is to a great extent the construct of the people who act in the world, perceive the world, or describe it or theorize about it. In a similar way to which linguistic champions considered reality as shaped or at least filtered by the language used by the people, some proponents of the visual perspective and some representatives of visual sociology treat pictures, icons, and images as shaped or at least distorted by the agents involved in visual practices. 'Cameras don't take pictures, people do' is the main argument. And people are subjective and culturally shaped creatures; they cannot escape their minds or their cultural milieu, and both are reflected in the pictures they take. Photographs, they say, are not representations of something existing independently, but presentations, emanations, embodiments of at least five circumstances:

1. The subjective reasons, intentions, and emotions – in brief the whole mind-set of the photographer.
2. The social status, role, and identity of the photographer – for example, as professional or amateur.
3. The cultural conventions, rules, and values constraining or facilitating certain photographic themes, aesthetic styles, or perspectives.
4. The wider context in which the picture is taken, such as travel, sightseeing, or family ritual.
5. The concretely situated interaction of the photographer and the subject – for example, the voyeurism of a hidden camera versus an open partnership.

The middle of the road position, closest it seems to common sense, may be called critical realism. It claims that there is a real world out there, and also the social world consisting of living people, their actions and interactions, the

material effects of their activity including the civilizational and technical environment, and also the organizations and institutions they build. But photographs are not simple mirror reflections of this world; they involve considerable selectivity and biases; they are constructed reflections depending upon subjective as well as cultural contexts. The first choice refers to the topic or theme of a picture. This is of course a personal decision linked with intentions, purposes, and interests. The theme of the picture may also reflect cultural conventions and rules: what is the right topic, what observations or experiences should be preserved, and so on. Then the second choice is the focus on an element that is considered central, that should be sharp and put in the middle or in another strategic location. The third decision has to do with framing. This involves some idea of priorities, because by framing we include what we consider important, worth recording, and cut off everything that lacks significance. Then the fourth and even more subtle decision concerns the depth of the field. This reflects further priorities of significance in the area already selected by framing. What is the foreground, and what can be left less sharp and clear as the background? Recent photographic technology, assuming that mass amateur photography is usually capturing people (family members or friends), makes this decision automatic by the tricks of so-called face recognition and moving autofocus tracing the actions of the people present. But switching on or off such features is the photographer's decision. The fifth choice refers to the lens we use. Are we interested in the context, environment, surroundings of the event or person captured, and hence we use a wide-angle lens; or are we only concerned with the object or person in its intrinsic details, detached from context. When some authors claim that for sociological photography the wide-angle lens is most useful, behind this choice there is a theoretical assertion that social events are always situated in complex contexts and cannot be properly understood ('seen') in isolation. The sixth choice is the shutter speed. It is related to our assumptions concerning the various speeds of social events in various contexts of social life. As the very term 'social life' suggests, when shooting society we are shooting movement, change. But the movement is of diverse tempo, rhythm, and duration. To grasp it adequately, the proper shutter speed is crucial. Finally, seventh, we have to make the most important decision, when to press the shutter. Social life is a fluid process, an incessant sequence or sometimes a chaos of events. To take a still photograph is to freeze that movement. As a famous press photographer, Henri Cartier-Bresson, emphasized, the mark of a great photograph is the right choice of a fleeting moment, which will never repeat itself but which is most loaded with meaning, most indicative of the problem we want to represent visually. Usually there is only one 'right moment.' Thus a middle-of-of the road perspective of critical realism, not falling into the trap of solipsism or pure constructivism, asserts that the photograph is of something real, which occurred in front of the lens, but admits at the same time that it is a selective reconstruction based on at least six choices taken by the photographer.

Another line of controversy of the fundamental, philosophical sort is the debate between universalism and cultural relativism. Universalism claims that pictures provide the language that can be understood across cultural or civilizational divisions. In other words, pictures are interculturally translatable. Such was the typical view of outstanding photographers. Andreas Feininger claims that "photography is picture-language, the only language that can be understood anywhere in the world" (2004: 3). And Martin Jay argues that there is "the capacity of the visual to break free from linguistic and cultural constraints." In his view, this is demonstrated in "the relative ease with which images cross the line," which "undermines the assumption that they are entirely relative to specific cultures, which are incommensurable with their neighbors" (Jay, 2002: 274). This intrinsic quality of pictures is enhanced by the process of globalization. It implies, among other consequences, the homogenization of cultures, or at least their hybridization or 'creolization' (Hannerz, 1996; Tomlinson, 1999). It means that no culture is now a self-contained, isolated unit, but rather a kind of a cultural melting pot: each consists of various components originating in many cultures. They provide bridges with the cultures of origin and facilitate intercultural translation. Pictures are the first to use this "transcultural mechanism of visual experience" (Jay, 2002), because they are not mediated by natural language, which is usually the most resistant core of autonomy within a culture. The visual culture is most sensitive to globalization (Mirzoeff, 1999; Mitchell, 2002).

The opponents to this view rallying under the banner of cultural relativism claim that the meaning of pictures, and also stylistic conventions, aesthetic preferences, perception rules, and reception regimes, are all shaped by culture, and cultures are unique wholes resisting intercultural mixing or translation. "It should be remembered that photography is a cultural product, despite its 'realistic' nature" (Wright, 2008: 50). Each picture may be understood only within the confines of its own culture, with the help of local cultural codes. There are various visual worlds separated from each other by impenetrable borders, a mosaic of visual monads.

In the debate between universalism and cultural relativism, the middle of the road position may be called incomplete universalism. The pictures, as more direct and unmediated vehicles of meaning, are more accessible for representatives of various cultures. Due to modernization and globalization, the ways pictures are taken become more uniform, as for example in the case of photography and a photo camera as a truly universal gadget. The content of photographs is also becoming similar, with the progressing homogenization of cultures and civilizations. All this makes 'reading,' interpreting, and understanding photographs more independent of cultural filters. But of course there remain local peculiarities, deep cultural stereotypes and prejudices, stylistic conventions, value priorities, and hierarchies of social issues – which become reflected both in the ways societies are depicted by photographs and in the manner in which photographs are contemplated and deciphered. In this area of remaining (or perhaps eternal) diversity, the claims of cultural relativism are relevant.

A Glimpse at the Future

The development of visual sociology is facilitated by the wider tendencies of its mother discipline. From a concern with abstract social systems and structures, sociology seems to move toward growing interest in everyday life and particularly the field of interpersonal relations. Simmel replaces Marx and Weber, and Goffman dethrones Parsons as the gurus of sociology for the twenty-first century. This new substantive focus is accompanied by the growing importance of qualitative methods instead of the purely quantitative and statistical style of earlier research.

For visual sociology this probably implies two trends. First, growing emphasis on visual methods as supplementary to more traditional qualitative research: recording observation by visual techniques, photo elicitation in interviews, the content analysis of the iconosphere, and studying private and family collections of photographs as a new type of personal documents (Prosser, 1998). Second, treating visual imagination as the necessary skill of all sociologists, independent of their field of research. And the visual imagination is a capacity of double translation: of pictures and visual impressions into sociological conceptual and theoretical frameworks; and the reverse, finding representations of sociological concepts and theories in images and observable features of social life. After all, there is not much more to society than what people do, individually and collectively. And most of what they do is visible. Such ontological commitments, typical it seems for recent sociology, provide a strong rationale for the future career of visual sociology.

Abstract

Human orientation in space is based primarily on vision: we are able to judge the size of an object even from a distance, its form and shape, and its egocentric distance. The set of all objects in the visual field together with the perceived spatial relationships between them is called visual space. To some extent, our perceptions are veridical. There are, however, marked and stable deviations from the physical relationships. This observation raises two questions: (1) are the regularities of perceived spatial relationships characterized by some particular geometry? and (2) if so, what are the psychophysical functions relating this geometry to the well-known Euclidean geometry of physical space?

Human orientation in space is based primarily on vision: we are able to judge the size of an object even from a distance, its form and shape, and its egocentric distance. The set of all objects in the visual field together with the 'perceived' spatial relationships between them is called 'visual space'. To some extent, our perceptions are veridical. There are, however, marked and stable deviations from the physical relationships. This observation raises two questions: are the regularities of perceived spatial relationships characterized by some particular geometry? and if so, what are the psychological functions relating this geometry to the well-known Euclidean geometry of physical space? This article is only concerned with the first question. It has four main parts. After some introductory and historical remarks on first observations and perceptual phenomena leading to the notion of non-Euclidean geometry of visual space in the early 1900s (Section 'Is Visual Space Non-Euclidean?') a formal characterization of what is meant by a geometry is given in the Section 'Geometry as a Mathematical Language for Spatial Structure'. The Section 'Theories on the Geometry of Visual Space' presents a discussion of theoretical developments in the field of geometries for visual space, in particular the theory of Luneburg (1947). The Section 'Empirical Results on Geometrical Structures of Visual Space' reviews related empirical investigations and results.

Is Visual Space Non-Euclidean?

The question of whether visual space is Euclidean was not formulated explicitly until the beginning of the twentieth century. Answers to this question, however, can be traced back as far as the ancient Greek philosophers. Suppes (1977) presents a list of classical contributions to this problem, starting with Euclid's theory of perspective (rated as a 'Yes' answer). His list contains a majority of 'No' statements, some undecided cases rated as 'not sure', and only a few 'Yes' conclusions, mainly from authors using philosophical arguments rather than empirical results. Strong evidence against Euclidean geometry as an appropriate description of the structure of visual space arose from observations in so-called alley experiments. Investigating the phenomenon of size constancy, Hillebrand (1902, cited in Lukas, 1996) asked subjects to arrange small light points in the horizontal plane along two lines such that they should form an alley-like configuration, running from two fixed points toward the observer. He used two similar tasks but with different instructions. The first was to match the 'horizontal distances' of points to make sure that, perceptually, the width of the alley should be perceived as equal at any egocentric distance (*D*-alley).

The second was to pay attention to the alley's right and left border and make sure that they are perceived as 'parallel straight lines' (*P*-alley). To Hillebrand's surprise, the two instructions led to different configurations. Both alley types were curved, with *D*-alleys consistently lying 'outside' the corresponding *P*-alleys (see **Figure 1**). Blumenfeld (1913, cited in Lukas, 1996) confirmed this finding and was the first to mention a far-reaching consequence: since in Euclidean geometry lines with constant distance everywhere are called parallel (and vice versa), visual space has to be non-Euclidean. Blumenfeld's geometric reasoning elicited a vivid discussion, but for more than 30 years thereafter, it was not worked out mathematically in any substantive way. Luneburg (1947) was the first to present both a complete geometrical framework for visual space, and explicit psychophysical functions that related physical and visual coordinates in order to explain the striking results of the alley experiments and other empirical facts in binocular space perception known at that time.

Geometry as a Mathematical Language for Spatial Structure

Within mathematics there are at least two different approaches to geometry, the 'synthetic' and the 'analytic'. In the spirit of Euclid's axiomatic approach, synthetic geometry is defined over a set of points and a set of straight lines as primitives by specifying a number of relations considered to be true. Over many centuries Euclid's axioms have been considered to be the only reasonable description for spatial relationships. They include incidence axioms (for example, any two distinct lines have at most one common point), order axioms, axioms concerning motion and congruity, metric axioms, and, finally, the famous parallel axiom stating that for any point P and any line g not containing P there is one and only one line g' through P parallel to (not intersecting) g. At the beginning of the nineteenth century, however, Gauss, Bolyai, and Lobachevski

Figure 1 Classical setting for alley experiments. P and P' are fixed points at eye level, L and R denote the observer's left and right eye, respectively. The subject adjusts movable points according to one of the criteria shown below (left: parallel alley, right: distance alley).

discovered independently that the parallel axiom can be replaced by the postulate that there exist at least two parallels, yielding a different type of geometry (later called 'hyperbolic'). Moreover it has been shown that even a third version of the parallel axiom, stating that any two lines have at least one point in common, is compatible with the remaining Euclidean axioms, and leads to an 'elliptic' geometry.

The properties of both types of non-Euclidean geometry are demonstrated easily by models that fulfill the respective set of axioms. A well-known model for an elliptic plane is the surface of a sphere in Euclidean space $I\mathbb{R}^3$, where the set of elliptic lines is defined as the set of all (Euclidean) great circles. Similarly, models for hyperbolic geometry can be constructed on surfaces with constant negative curvature in $I\mathbb{R}^3$ (for example, saddle-shaped surfaces). Hyperbolic geometry is therefore said to have constant negative curvature, whereas elliptic geometry is characterized by its constant positive curvature.

Theories on the Geometry of Visual Space

Let V be the set of all points in the three-dimensional physical space which a fixed observer can see without moving the head. If x, y, z denote the Euclidean coordinates in physical space, then V is a subset of the positive half space $y > 0$ right in front of the observer. The origin of the coordinate system is interpreted as the egocenter of the observer and is assumed to lie in the closure of V, the x-axis denotes the direction from left to right, and the z-axis corresponds to the vertical axis. We restrict the following discussion to the horizontal plane $z = 0$ at eye level. The well-known Euclidean metric d_{phys} represents the physical distances in V.

In his famous attempt to represent the perceptual structure of binocular visual space geometrically, Luneburg (1947) starts out with the basic assumption that in addition to d_{phys} there exists some metric d_{vis} on V that represents the 'perceived' spatial structure. If γ and ϕ denote binocular parallax and bipolar latitude, respectively, his theory can be summarized by the following basic hypotheses:

LH1 There exists a Riemannian metric d_{vis} on the visual field V that represents perceived distances. The geodesics of d_{vis} are perceived as straight lines.

LH2 The visual space (V, d_{vis}) has constant Gaussian curvature K.

LH3 The perceived distance d_{vis} $(0, P)$ of point P to the observer is a function of the bipolar parallax only.

LH4 The ϕ-translations (γ, ϕ)–$(\gamma, \phi + \text{const})$ are visual isometries (leave all perceived distances unchanged).

LH5 The γ-translations (γ, ϕ)–$(\gamma + \text{const}, \phi)$ are angle-preserving.

Assumption LH1 provides the basis for the remaining assumptions: In a Riemannian metric space a coordinate system can be introduced that allows numerical representations for any geometrical objects such as lines, angles, triangles, or distances. LH2 restricts the discussion to geometries that are constantly curved everywhere. The remaining assumptions LH3 through LH5 define the psychophysical relationship between (physical) stimulus space and (perceptual) visual space. LH3 implies, for example, that points lying on a Vieth–Müller circle (VMC) (a circle containing the nodal points of the observers eyes) are perceived as equidistant to the observer because they have the same bipolar parallax γ. These latter assumptions are explained and discussed extensively in Binocular Space Perception Models.

Eschenburg (1980) gave a complete proof of Luneburg's conjecture that LH1 through LH5 uniquely determine the metric d_{vis} by two parameters K and σ up to equivalence. More specifically, the line element of the metric is represented in terms of the bipolar coordinates ϕ and γ by

$$\mathrm{d}s^2 = \frac{2\sigma^2(\mathrm{d}\gamma^2 + \mathrm{d}\phi^2)}{e^{\sigma\gamma} + Ke^{-\sigma\gamma}}$$

(Eschenburg, 1980: p. 7). K denotes the Gaussian curvature of visual space, and σ is an individual scaling factor.

Empirical Results on Geometrical Structures of Visual Space

Whereas LH3 through LH5 are closely connected to the psychophysical relationship between physical and visual coordinates, LH1 and LH2 define the inner geometry of visual space. Empirical investigations have concentrated on two

questions: (1) is K constant? (2) if so, is $K = 0$ indicating Euclidean geometry, or $K < 0$ (hyperbolic geometry) or $K > 0$ (elliptic space)? The early observations of distance alleys lying consistently outside the corresponding parallel alleys are only compatible with hyperbolic geometries (Indow and Watanabe, 1984). Direct numerical estimates for K can be derived from alley experiments or from so called 3- and 4-point experiments using double VMC suggested by Luneburg (1947) (see **Figure 2**). Using these methods K has mostly been found to be negative (Hardy, Blank, Boeder, Rand, and Rittler, 1953, cited in Lukas, 1996). However, numerical estimates of K cannot always reliably be reproduced in repeated measurements, estimates resulting from 3- and 4-point experiments are not valid predictors for data obtained from alley experiments, and experiments over large egocentric distance ranges coincide qualitatively but not quantitatively (Indow, 1991).

Moreover, for a test of LH2, numerical estimates of K are only of limited utility, because they presuppose the psychophysical mapping functions. Several methods have been suggested to test LH1 and LH2 independently from the remaining assumptions. In the triangle method used by Blank (1961) subjects had to bisect two sides of a given triangle *ABC*. Six of a total of seven subjects gave judgments indicating a negative curvature. However, the results seem to depend on the size of the triangle. Using the same method, Higashiyama (1981) found strong variations in curvature depending on lateral positions of the triangles and their distance from the observer. Battro et al. (1976) used stakes to produce experimental alleys of variable size in large open fields in natural environments. The curvature of visual space did not show a negative constant value. In addition, the results of experiments with equidistant lines and visual triangles under these viewing conditions also invalidated the constant curvature assumption.

Figure 2 Experimental procedure in 4-point experiments. P_1, P_2, and P_3 are fixed on the Vieth–Müller circles $\gamma = \gamma_1$ and $\gamma = \gamma_2$, respectively. P_4 is adjusted by an observer such that P_4P_3 matches P_1P_2 perceptually.

Luneburg (1947) used quite a different argument and referred to the fact that Riemannian spaces with constant curvature are often characterized geometrically by a property called free mobility (any configuration can be moved to any position in space without changing the shape). Eschenburg (1980) showed that, contrary to Luneburg's argumentation, the existence of visual isometries alone does not guarantee free mobility in a strict sense. In Blank's (1958, cited in Blank, 1961) axiomatic version of Luneburg's theory, free mobility is guaranteed by an axiom that implies both the so-called Desarguesian property, and constant curvature in Riemannian spaces. Empirical consequences of this axiom have been tested successfully by Foley (1964, cited in Foley, 1972). However, a much stronger test in subsequent experiments failed (Foley, 1972). Lukas (1996) gave detailed arguments as to why the first test might have been too weak and the latter one unreasonably strong. From an empirical point of view Eschenburg (1980) provides the most powerful and sensitive test of the constant curvature hypothesis. He shows that an appropriate combination of the double VMC-experiments produces necessary and sufficient conditions for LH2. Experimental tests of these conditions reported in Lukas (1996) reflect a situation that seems to characterize most results in this field: the data are nicely fitted qualitatively by the predictions using constant curvature, yet there are numerically small, but statistically significant deviations.

Nevertheless, there are few models in the literature that try to generalize Luneburg's geometrical assumptions (contrary to his psychophysical assumptions, which have been relaxed in several attempts). Yamazaki (1987) developed a concrete non-Riemannian geometry and suggested its application to visual space. Because this model does not use the concept of length, its utility for empirical research seems limited.

A different approach is reported in Lukas (1996). Starting out with an axiomatic analysis of size constancy, he defines 'apparent distance' in terms of modern measurement (*see* Measurement, Representational Theory of) and shows that a very weak invariance condition resembling Luneburg's isei-conic transformations (defined in LH4 and LH5) forces the geometric structure of visual space to be Euclidean.

Conclusion and Future Directions

Critical reviews of empirical results seem to indicate that there is little hope of characterizing visual space globally by one particular geometry. Suppes (1995) concludes that visual space is context-dependent and no reasonable simple set of axioms in the spirit of synthetic geometry can be given for the structure of visual space. This view seems to be supported by recent results from Zimmer (1998). In a series of experiments, subjects failed in a test of very basic requirement of 'betweenness' indicating that not even simple order structures on a straight line can be assumed to hold a priori. Nowadays, geometric models in visual perception are actively discussed almost exclusively in the context of mathematical psychology and foundational aspects of science. The main stream of research in vision has obviously shifted to computational models (*see* Vision, Low Level Theory of) and the analysis of cognitive processes underlying human performance in spatial perception.

Visual Streams: Dorsal and Ventral

A David Milner, Durham University, Durham, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The human brain contains two quasi-distinct visual systems operating in parallel, each originating in the primary visual cortex. The ventral (occipitotemporal) stream, codes information as a semantic representation suitable for storage and for deploying off-line in cognitive processes such as imagining, recognizing, and planning. It provides the visual contents of our perceptual experience. The dorsal (occipitoparietal) stream serves the more immediate function of guiding our movements visually from moment to moment, and so needs to code transitory 'here and now' information in an egocentric format. Its contents appear not to inform cognitive processing, and to be inaccessible to conscious monitoring.

Our Visual Inheritance

Evolution has provided primates with a patchwork of visual areas occupying almost 50% of the posterior half of the cerebral cortex. Despite the undoubted complexity of the interconnections among these different areas, two broad 'streams' of processing have been identified in the macaque monkey brain, each originating from the primary visual area (V1): a ventral stream projecting eventually to the inferior temporal cortex (ITC), and a dorsal stream projecting to the posterior parietal cortex (PPC). The dorsal stream also receives visual inputs via a number of subcortical visual structures, notably the superior colliculus in the midbrain and the pulvinar nucleus of the thalamus (Figure 1).

Functional Evidence: Primate Neurobehavioral Studies

In their seminal 1982 paper, which first explicitly identified the two streams of visual processing, Leslie Ungerleider and Mortimer Mishkin (1982) proposed that the two systems play complementary roles in the perception of incoming visual information. According to their account, the ventral stream governs the recognition of objects, whereas the dorsal stream mediates the localization of those same objects. Apparent support for this idea came from work with monkeys. Lesions of ITC produced deficits in the animal's ability to discriminate visually between objects, but had less effect on its performance on a task requiring it to register the location of a 'landmark' located between two alternative response sites. Conversely, lesions of the PPC produced deficits in performance on the landmark task, but did not affect object discrimination learning. Although the evidence available at the time was largely consistent with Ungerleider and Mishkin's (1982) 'what versus where' proposal, the results of subsequent research fit better with a distinction not between subdomains of perception, but between perception on the one hand and the guidance of action on the other (Jeannerod, 1997; Milner and Goodale, 2006). For example, subsequent research showed that monkeys with PPC lesions fail to register not only the *location* of a 'landmark' object but also its visual features as well, and show a loss of overt orienting movements toward the landmark. In other words PPC lesions cause a fundamental deficit of visual orienting, thereby limiting what items in the visual environment are attended to and processed. The deficit on the landmark task is primarily one of visually guided orienting movements, not one of perception – spatial or otherwise.

Figure 1 A schematic diagram of the two streams of visual processing in primate cerebral cortex. The ventral stream receives nearly all of its visual input from the primary visual cortex (V1), which in turn receives its input from the lateral geniculate nucleus (LGNd) of the thalamus. The dorsal stream also receives input from V1, but in addition gets substantial inputs from the superior colliculus (SC) via the pulvinar (Pulv), another nucleus in the thalamus. This pathway and others shown on the diagram remain intact in patients who have damage to V1, enabling certain unconscious visual abilities to survive such damage. The arrows on the inset photograph of the human brain show the approximate route of the two streams within the cerebral hemispheres.

Functional Evidence: Visual Neurons in the Ventral and Dorsal Streams

Neurons in ventral-stream areas culminating in ITC are tuned to the features of objects, and many of them show remarkable categorical specificity; for example, for faces or for bodily movements. Many of these cells maintain their selectivity irrespective of viewpoint, retinal image size, and lighting conditions. These ventral-stream neurons are not affected directly by the monkey's concurrent behavior, though many are modulated by how often the visual stimulus has been encountered, and by its association with reward. Thus the evidence strongly suggests that the ventral stream is more

concerned with the enduring characteristics and significance of objects than with moment-to-moment changes in the visual array.

Neurons in the dorsal stream show quite different properties from those in the ventral stream. Neurons in the PPC are activated by visual stimuli according to the response the monkey makes to those stimuli. For example, some cells respond when the stimulus is the target of an arm reach; others when it is the object of a grasp response; others when it is the target of a saccadic eye movement; others when the stimulus is moving and elicits a slow pursuit eye movement; and still others when the stimulus is stationary and becomes the object of fixed gaze (Jeannerod, 1997; Milner and Goodale, 2006). Other neurons, located in the same region as those associated with saccadic eye movements, respond in association with shifts of visual attention to fresh locations across the visual field.

These findings can readily explain why posterior parietal lesions impair landmark task performance: the monkey has lost the neural machinery for making head or eye movements toward the landmark, thereby failing to attend to it and learn its significance. They also explain the most immediately striking and long-known effects of PPC lesions – an inability to reach accurately for a moving or stationary food morsel, and a failure to shape and orient the hand and fingers appropriately to grasp or pick up the item. The evidence now shows clearly that visual networks in the dorsal stream compute more than just spatial location – they process the orientation and intrinsic geometry of visual stimuli as well, all in the service of efficient and well-coordinated action.

It should be noted that there are some visual areas that do not fit neatly into either stream. Although by some definitions the area known as the 'middle temporal' (MT) or 'visual area 5' (V5) lies in the dorsal stream, it behaves very much as if it lies in neither stream, or perhaps in both. Anatomically it is monosynaptically and reciprocally connected with the relatively unspecialized early visual areas V1, V2, and V3, and it sends projections directly to several areas in both dorsal and ventral streams. At first sight area MT looks like a ventral-stream area in being highly specialized for processing one particular visual property, namely motion, but research has shown that it provides this information both to dorsal stream areas mediating one's ocular and manual tracking of moving stimuli, and to ventral-stream areas concerned with putting the '4th dimension' into our conscious perception. This latter convergence in certain higher reaches of the ventral stream, notably within depths and banks of the superior temporal sulcus, allows static information (e.g., about objects, faces, and bodies) to be integrated with their dynamic properties, enabling us to recognize facial expressions and bodily actions.

Evidence from Neuroimaging Research

Functional neuroimaging of the visual brain in humans has advanced dramatically in recent years. Functional MRI (fMRI) in particular has provided extensive supporting evidence for the division of labor between the two visual streams that is described here. First, numerous studies beginning with Rafi Malach and his colleagues in 1995, have established a close association between ventral-stream activation and different aspects of visual perception (Grill-Spector and Malach, 2004). One area, for example, known as the lateral occipital (LO) area, is activated whenever the observer is looking at pictures of objects, and is localized by subtracting the brain activation pattern that results from viewing scrambled versions of the same objects. The net activations remaining after the subtraction indicate the regions concerned with shape perception in healthy individuals. Separate areas within the ventral stream are selectively activated by other visual categories (faces, hands, bodies, scenes), or by particular visual features (color, texture). Nancy Kanwisher and her colleagues, for example, discovered in the 1990s that faces preferentially activate an area in the ventral occipitotemporal region that has become known as the 'fusiform face area' (FFA). In other work, they found that places and buildings preferentially activate an area lying more medially, frequently named the 'parahippocampal place area' (PPA).

No area in the dorsal stream has been found to share this kind of close association with a dimension or category of visual perception. Instead, recent work has shown that areas within the dorsal stream are selectively activated when people actively respond to their visual environment in particular ways, whether by reaching out to targets and grasping objects or simply making rapid eye movements toward targets. Thus in a series of studies during the 2000s, Jody Culham and her colleagues have established that an area known as 'the human homologue of the monkey's anterior intraparietal area' (hAIP) is closely associated with the visual guidance of object grasping. At the same time they have also established that the 'superior parieto-occipital area' (SPOC) is linked with the reaching movements of the arm toward a visual target (Culham et al., 2006).

Visuomotor Deficits following Brain Damage in Humans

The first systematic description of a patient with bilateral PPC damage was published by Rudolph Bálint in 1909. Bálint's patient was unable to reach accurately toward objects with his right hand. In many respects this disorder, which Bálint called optic ataxia, resembles the visuomotor problems of the PPC-lesioned monkey. Humans with PPC damage not only fail to reach in the right direction, but also have difficulty orienting their wrist and forming their manual grasp appropriately to pick up particular individual objects (Jeannerod, 1997). This inability to use visual information to preshape the hand while reaching out means the patient often has to grope for an object. For example, they make errors in hand rotation as they try to reach toward and through a large oriented slot. Also, they often fail to show the normal unconscious opening of the hand in proportion to the size of different objects when reaching out to grasp them. Yet despite such visuomotor failures, these patients often have little difficulty in giving perceptual reports of the orientation and location of those very objects they fail to grasp. Parallel problems have been documented in controlling reaching and grasping movements so as to avoid potential obstacles lying close to the target object. Again this occurs without any concomitant

problem in judging where the potential obstacles are located. It thus seems that dorsal stream damage in humans, as in animals, selectively affects visually guided action, across both spatial and nonspatial domains.

Perceptual Deficits following Brain Damage in Humans

On the other side of the equation, damage to the ventral stream typically impairs aspects of visual perception. These range from difficulties in color or texture discrimination, to problems in visual recognition, in other words to different varieties of visual agnosia. In this context the condition known as visual form agnosia has been particularly well studied. These patients not only fail to recognize faces or objects, they fail even to distinguish simple geometric shapes. One such patient, DF, has been studied extensively over more than 20 years (Milner and Goodale, 2006; Goodale and Milner, 2013). The scientific value of these studies hinges on DF's uniquely fortuitous pattern of brain damage, which gives rise to severe visual form agnosia as an isolated symptom, in the absence of any motor impairment or notable cognitive loss. Most other similar patients in the literature either have a less severe impairment of shape discrimination, or suffer from cognitive or motor impairments.

What DF can do is as important as what she cannot. For example, her attempts to make a perceptual report of the orientation of an oriented slot show little relationship to its actual orientation, whether her reports are made verbally or by manual means. However, when she is asked to insert her hand or a hand-held card into the slot, she effortlessly moves her hand or the card toward the slot in the correct orientation, and inserts it smoothly. Indeed her hand begins to rotate in the appropriate direction as soon as it leaves the start position. In short, although she cannot report the orientation of the slot, she can act upon it with considerable skill.

We observed similar dissociations between perceptual report and visuomotor control when DF was asked to deal with properties of objects such as their size and shape (Goodale et al., 1991). Thus she showed excellent visually controlled anticipatory hand posture when reaching out to pick up blocks of different sizes that she could not distinguish perceptually. Just like healthy subjects, DF adjusted her finger–thumb separation well in advance of contacting the object, doing so in the normal linear fashion in relation to the target width. Yet when she was asked to use her finger and thumb to give a perceptual indication of the object's width, her responses were unrelated to the actual stimulus dimensions, and showed high variation from trial to trial.

Various studies of DF show that she is able to carry out many actions that are governed by visual information of which she has no perceptual awareness. But we have found that this is only true of actions that are directly targeted at the visual stimulus. She cannot successfully use the same visual information to guide a response that is superficially similar but is displaced to another location. Presumably the difference is that this kind of displaced response is arbitrary or symbolic in nature. DF seems to depend on a dedicated visuomotor processing system that will normally only come into play when she carries out natural goal-directed actions. She has no explicit visual awareness of the shapes and sizes that guide her responses when she is using this preserved visuomotor system.

There are temporal as well as spatial limits on DF's ability to drive her motor behavior visually. In one study, DF was shown a rectangular block, which was then removed while her eyes were closed, after which she reached out and pretended to grasp it. The preparatory grip size of normal subjects still correlates well with object width even after a 30 s delay. In DF, however, all evidence of grip scaling during her reaches had evaporated even after a delay of 2 s. The problem seems to be that this kind of delayed reach is again not a natural goal-directed movement, instead requiring subjects to recall the object they were shown earlier and then to 'pantomime' what it would be like to grasp it. DF simply does not have the wherewithal to implement such a strategy: to put it starkly, she cannot recall the appearance of something that she has not perceived in the first place. Apparently her preserved visuomotor brain can only respond to present or imminent states of the visual world, and routinely disregards past states, which typically will no longer be relevant to the task in hand.

Parenthetically, a complementary improvement in both reaching accuracy and grip scaling has been recorded in two patients with optic ataxia when making pantomimed responses after a 5 s delay, as opposed to acting immediately (Milner and Goodale, 2006). Presumably the delay forced these patients, who had sustained bilateral damage to the PPC, to use their (relatively) undamaged ventral system, effectively overriding the imperfect visuomotor control that would be provided by their damaged dorsal stream.

We have carried out several experiments using fMRI with DF herself in recent years. First we discovered using high-resolution structural MRI that the densest areas of damage in her brain are concentrated bilaterally in a region that corresponds well to the location of area LO in the normal brain (James et al., 2003). As mentioned earlier, area LO is activated in association with the perception of object shape in healthy individuals. Clearly therefore the loss of area LO would readily explain DF's visual form agnosia – effectively she would have lost the cerebral machinery for constructing percepts of whole objects from their elements. This interpretation was upheld when we carried out a fMRI experiment with DF herself, making the same contrast between viewing intact and scrambled objects that defines area LO in healthy subjects. The absence of any net activation in this experiment (James et al., 2003) established that her brain damage has effectively deprived her of the neural circuitry required to form percepts of intact objects: her brain shows no sign of being able to distinguish intact objects from scrambled ones. The data also allow us to frame an important converse argument. Normally, fMRI only allows us to make *correlations* between a particular pattern of brain activation and some particular psychological process. But if a patient who has evidently lost area LO bilaterally has also lost the ability to perceive object shape, then we can make a *causal* inference. We already knew that area LO is active when we perceive objects: now we can argue that LO forms an *essential* element in the healthy brain's circuitry for perceiving the shapes of objects. Its activity is not merely an epiphenomenon of shape perception.

We also tested whether DF's dorsal stream was activated when she reached out and grasped objects. We confirmed that area hAIP is indeed active when DF grasps objects under visual guidance, as is her area SPOC when she simply reaches out to touch objects (James et al., 2003). These further data provide strong confirmatory evidence for our hypothesis that the calibration of DF's many visually guided skills depends on the intactness of visuomotor control mechanisms within her dorsal stream.

Operation of the Two Streams in Normal Vision

It is most likely that healthy observers too, like DF, control their actions using visual information that is not present in their awareness. In healthy people of course, this visuomotor processing will be operating in parallel with intact perceptual processing within the ventral stream – with minimal interaction between the two. In fact the dorsal stream seems to act in relative isolation not only from the perceptual system, but also from the brain's acquired database about the visual world.

The implicit assumptions that underlie the brain's ability to confer stability and constancy on our perceptual world are based on such stored real-world knowledge. These assumptions sometimes cause us to misjudge what we see, as when a shift in a large frame makes a stationary spot inside it seem to shift in the opposite direction. In contrast, the dorsal system, by and large, is not deceived by such spatial illusions. Instead, it directs our saccadic eye movements and hand movements to where a target really is, instead of where our perceptual system tells us it is. Similarly, under appropriate circumstances geometric illusions can be seen to affect visually guided reaching and grasping far less – if at all – than they affect perceptual judgments (Goodale, 2008). In other words, you may perceive an object as bigger than it really is, but you open your finger–thumb grip correctly when reaching for it. In one study by Tzvi Ganel and his colleagues, the stimuli were adjusted such that one looked larger than the other, although actually physically smaller due to the influence of the Ebbinghaus illusion (**Figure 2**). The results were dramatic and thoroughly convincing: perceptual judgments went one way, while grasp calibration went the opposite way. No other model of visual function predicts, or can plausibly explain, such observations.

In another study, Richard Dyde and I (2003) compared two illusions of visual orientation (**Figure 3**). One, the simultaneous tilt illusion (STI), was used because it is believed to originate in early visual cortex, as a result of lateral interactions between columns of neurons sensitive to slightly different stimulus orientations. We argued that this illusion should therefore be 'passed on' to both visual streams, and so deceive action as much as perception. The other, the rod-and-frame illusion (RFI), was chosen because it is believed to be generated in the higher reaches of the perceptual system, and so, ex-hypothesi, anatomically well within the ventral stream. We reasoned that the orientation of responses directed at the central stimulus in the RFI should be immune to the illusion, despite there being a strong effect on perception. The results bore out these predictions. We found a similar strength of *perceptual* illusion in both STI and RFI, but as predicted, only those movements made toward the STI were deceived by the illusion, and indeed they were deceived to an extent very similar to the subjective STI illusion.

Figure 2 In the Ebbinghaus illusion, shown here, the two middle circles in the top two arrays appear to be different in size even though they are actually physically identical. The two middle circles in the bottom display appear to be identical but their real size is actually different. (To convince yourself of this, view each display through a piece of paper with two holes cut in it that reveal only the two central circles.)

Figure 3 The 'simultaneous tilt illusion' (top) and the 'rod-and-frame illusion' (bottom). In both illusions, we see the stripes or central line to be tilted in opposite directions according the tilt of striped background (top) or the tilt of the frame (bottom). The reasons for this, however, are different for the two illusions. The simultaneous tilt illusion is probably the result of local inhibitory effects within the primary visual cortex, and therefore would be passed on to both visual streams. As a consequence this illusion affects both perception and action. The rod-and-frame illusion, however, depends on the same kinds of perceptual mechanisms as the pictorial illusions already mentioned, and like those, affects perception but not action.

It seems that the processing accomplished by the ventral stream both generates, and is in turn informed by, stored abstract visual knowledge about objects and their spatial relationships. It may be that these 'top-down' influences, and indeed the continual two-way traffic within the ventral stream, are what render our perceptual representations accessible to awareness (Lamme, 2006). This would fit neatly with the idea that coded

descriptions of enduring object properties ('invariants'), rather than transitory egocentric views, are needed for mental manipulations like the planning of action sequences and the mental rehearsal of alternative courses of action.

Perception and Action

The distinction between the visual roles of the dorsal and ventral streams has forced a careful consideration of what constitutes a simple visually guided act. As mentioned earlier, the dorsal stream is associated with immediate goal-directed movements, but is unable to guide movements based on visual information separated either spatially or temporally from the act itself. In addition, the dorsal stream's role seems to be limited to the guidance of movements that are well practiced. The use of visual illusions illustrates this well. Claudia Gonzalez and her colleagues (2008) showed that unfamiliar grasps made by the thumb and ring finger were subject to visual illusions like the Ebbinghaus, whereas natural grasps between forefinger and thumb were not (Goodale, 2008). She also found that right-handers using the left hand are also subject to visual illusions to which their preferred hand is immune. Recent evidence from Thomas Schenk suggests further that an action carried out 'in thin air', even when guided by a virtual image of a real object apparently located at the same place as the action, may require mediation by the ventral stream. At any rate, DF fails to show visual calibration of her grip size under these circumstances, when there is nothing tangible to grasp (despite appearances). Evidently the dorsal stream is not so easily fooled into treating a virtual image as real. It is deeply grounded in hard physical reality. In contrast of course, the ventral stream has no problem with virtual reality – as testified by our insatiable thirst for movies and television.

Integration of Visual Function

Although the dorsal and ventral streams have separate functions, there are multiple connections between them, and indeed adaptive goal-directed behavior in humans and other primates must depend on a successful integration of their complementary contributions. Thus the execution of a goal-directed action might depend on dedicated control systems in the dorsal stream, but the selection of appropriate goal objects and the action to be performed depends on the perceptual machinery of the ventral stream. Recent research suggests that direct connections from areas in the ventral stream to area hAIP may permit the dorsal stream mechanisms controlling grasping not only to calibrate grip size, but also to calibrate the grip force that needs to be applied by the fingers to grasp objects composed of different materials. Only the ventral stream seems to analyze the surface color and texture of objects, thereby enabling the brain to infer the 'stuff' that a given object is made of. A grip suitable for picking up a hardball is not going to work well with a ripe tomato or for lifting a ball of polystyrene.

Of course, the fact that ventral stream information may be useful to modulate dorsal stream processing by bringing visual 'semantics' into play, does not imply that it also brings conscious visual content with it. The evidence we have points to a rather strict segregation of conscious access, with only the ventral stream able to bring its products into visual phenomenology. fMRI has helped to confirm this segregation.

As mentioned earlier, the use of fMRI has delineated several specialized ventral-stream areas, two of which are the FFA, and the PPA, respectively activated by pictures of faces, and by pictures of buildings or scenes. Researchers have used this difference between the two areas to study the changes in visual consciousness during 'binocular rivalry.' They presented pictures of a face and a house simultaneously, one picture to each eye (**Figure 4**). Sometimes subjects would see the house and sometimes the face, but almost never both at once. They were asked to press a key whenever one percept was replaced by the other. Whenever they reported a switch to seeing the face, there was increased activity in their FFA – but when they reported seeing the house instead, there was more activity in their PPA. In other words, the activity in the FFA and the PPA reflected what they consciously perceived, not what was on their retina (which never changed).

Research like this demonstrates that areas in the ventral stream are associated with conscious visual processing, but in most cases the dorsal stream has not been tested. Yet pictures of objects can activate areas in the dorsal stream too – including area hAIP, where visual information about objects drives the formation of our grasping movements. Only recently have researchers asked the question whether levels of activation in these dorsal stream areas are correlated with awareness and unawareness just like activations in the ventral stream. Fang Fang and Sheng He (2005), instead of pitting two different patterns against each other, one shown to the left eye and the other to the right, created 'interocular suppression' by presenting high-contrast dynamic noise to just one eye. This visual noise prevented the observers from consciously seeing pictures of objects that were presented to the other eye. Yet these pictures still elicited substantial fMRI activation in the dorsal stream – and more importantly this activation was just as great as when there was no interocular suppression (i.e., the pictures were consciously perceived). As would be expected from previous work, however, Fang and He did find large differences in activation in the ventral-stream area LO between these 'aware' and 'unaware' testing conditions. So it seems that object-related areas in the dorsal stream respond to visual objects to the same extent, quite independently of whether the visual information is perceived consciously or not. That perceptual distinction seems to be entirely the province of the ventral stream, acting in parallel.

On the other hand, as was noted earlier, the lateral intraparietal area is not only concerned with guiding visually elicited saccadic eye movements, it also guides switches of our visual attention to new locations, even when our eyes remain stationary. Since this area is located in the dorsal stream, it has sometimes been argued that the dorsal stream must play a role in determining the contents of our visual consciousness. Indeed in experiments using binocular rivalry, fMRI activations in both the dorsal stream and associated areas in the frontal lobes are seen whenever there is a shift of perception from one of the two stimulus patterns to the other. But of course this activation does not correlate with the *direction* of the shift – it is just the same whether there is shift from percept A to percept B or from B to A. Dorsal stream activity determines our perceptual experience only indirectly – by switching activation

Figure 4 This figure shows the results of a fMRI study using binocular rivalry. Brain activation was measured in the FFA (selective for faces) and the PPA (selective for buildings) when observers viewed rivalrous images of a face and of a house (top left). The level of activation switched between the two brain areas in step with what the observers reported seeing (top right). The changes in activation in the two areas were just the same as those seen when the two pictures were presented successively (rather than simultaneously) in a manner mimicking the alternations of rivalry (bottom left and right). between different perceptual representations within the ventral stream. It is uncorrelated with the current contents of our perception.

In summary, only the perceptual system in the ventral stream can provide the raw materials suitable for thought processes to act upon, and suitable for storage in memory. In contrast, the dorsal stream provides the raw materials for guiding action and switches of attention. It is designed to guide actions purely in the 'here and now,' and its products are discarded after use since they have to be constantly superseded by new ones.

Visual Turn

Francesco Ventrella, University of Sussex, Brighton, UK

Abstract

The visual turn encompasses a number of critical concerns in the humanities and social sciences, which explore visuality as both socially constructed experience, and as what makes social experience possible. The visual does not simply imply what can be seen by the eye as part of the phenomenal world, but it also refers to the social organization, partition, and administration of looking. As a challenge to the alleged transparency of images, the visual turn represents a critique of realism across media and disciplines.

Turning the Visual Turn

The visual turn encompasses a number of critical concerns in the humanities and social sciences, which explore visuality as both socially constructed experience, and as what makes social experience possible. The term visuality does not simply refer to a 'social practice of vision' but to a specific technique of power that can be visualized in history. How did visual culture convey representations of homosexuality before there was even a name for it? Why is the visual discourse of ethnicity often associated with attributes bearing a reference to authenticity, naturalness, and documentary realism? Such ways of interrogating the visual aim at reorganizing the relationship between what enters the field of vision and our abilities to interpret it. Seeing is not necessarily a pivoted and perspectival mode of apprehension, but an extended and expanded activity that turns images into signifying practices. Images present themselves as intermedial events that do not originate within, although they might not transcend from genres, traditions, canons, and conventions. As an independent and abstract term, the visual does not simply imply what can be seen by the eye as part of the phenomenal world, but it also refers to the social organization, partition, and administration of looking. Thus, the visual is also the medium that makes social experience possible by making visible social shifters such as gender, sex, class, ethnicity, race, age, ability, etc.

Within the field of vision, both material and immaterial representations can be approached in relation to regimes of visuality (what can be seen and how, under which circumstances), and in conjunction with the most disparate media of portrayal, depiction, symbolization, and simulation that make things visible (painting, speech, photography, clothing, cinema, dream narratives, writing, the Internet, etc.). The intellectual history of visuality is embedded in a number of disciplinary practices traditionally ranging from art history, philosophy, psychology, aesthetics, anthropology, and rhetorics. Its displaced genealogy is reflected in the effects that the visual turn has had across the disciplines. The lack of a common disciplinary object of visual culture has triggered a series of animated discussions among scholars. Yet, as W.J.T. Mitchell seems to suggest, the departure of a common object could be fortunate if it accompanies the emergence of a common objective to overcome "the veil of familiarity and self-evidence that surrounds the experience of seeing" (2002). The visual turn challenges the idea that images are transparent and obvious; the visual is turned every time seeing is displayed to make it available to analysis.

Genealogies of the Visual Turn

During the 1970s, an awareness about the intermediality of the visual initially triggered a shift away from research methodologies traditionally organized in monolithic academic encampments. Svetlana Alpers employed the term 'visual culture' with the aim to interrupt the seemingly natural link between works of visual art and their historical antecedents (1996). By this move, Alpers wanted to shift the priority from a history of art told by the works alone, on to a history of art which would intersect modes of visualization and apperception, and the way in which these too are inherently and structurally cultural phenomena. Visual texts should thus be interpreted in relation not only to the way in which one culture makes itself visible, but also to the way in which culture conceives of representation and representing as ways of knowing.

Such changes would be quickly registered in the emerging fields of film studies and cultural studies. The social history of art in Britain was particularly receptive to the role of ideology in the production and reception of artifacts, and started to trouble the distinction between high art and popular culture, thus hindering the conservative aesthetic canons of appreciation through a critical analysis of the politics of representation. Journals like *Screen* and *Block* record a number of pivotal contributions to the analysis of visual culture, often written with a pedagogical purpose to encourage critical teaching. Particularly important for these discussions was the theoretical input, deriving from "a combination of work on representation as a structure and process of ideology producing subject positions, and the social disciplining of technologies and regimes of power having real effects upon our lives and experiences" (Bird et al., 1996). The politicized voice of these journals, and the involvement with psychoanalysis, Marxist theory and semiotics was partly grown from a dialogue with other journals in continental Europe, notably France. The interdisciplinary journal *Tel Quel*, featuring contributions from theorists like Julia Kristeva and Hubert Damisch, will prove extremely influential for the development of the visual turn, on both sides of the Atlantic (Ffrench and Lack, 1998). Today, visual culture

is still committed to analyzing the commodification of the networks of production and exchange of visual culture, and attempts to avoid the reproduction of "value for transnational capital" (Mirzoeff, 2003).

The visual turn, and cognate phrases such as the 'pictorial turn' and the 'iconic turn', is not circumscribed to a specific academic discipline, but it envelops a wider array of interests that can be located in relatively recent transdisciplinary fields often referred to as visual studies, visual theory, and visual culture studies (Mitchell, 1994; Holly, 1996; Jay, 2002; Elkins, 2003; Moxey, 2008; Smith, 2008). There seems to be a general agreement that the visual turn has been somehow triggered by the ubiquitous presence of images, arguing that since "Western culture has come to be dominated by visual rather than oral or textual media" (Cartwright and Sturken, 2001), it has become possible to claim that "modern life takes place onscreen" (Mirzoeff, 1999). However, the spectacularization of life is not solely a product of contemporary visuality, but intersects with the historical layers of power relations that structure human imagination, and even fantasies.

Whither Historical Objectives?

Other scholars, particularly in North America, prefer to postpone the moment of the visual turn to the early 1990s (Mitchell, 1994; Jay, 2002), and identify a twofold emergence of visual studies in both the crisis of traditional disciplines and the spreading of new visual objects. Nicholas Mirzoeff (1999), in particular, has urged academics to acknowledge the need for the humanities to respond to a visual crisis arising from the excess of visual artifacts that were being made available by digital technologies. James Elkins (1999) too supports this idea by stressing not only the effects on 'visual literacy' deriving from the profusion of images, but also the changing quality of images we create and consume. The question must be asked whether the visual turn is a response to historical conditions that have changed visual experience, or it is a methodological revision of old issues. In fact, some have objected that the inundation of images in contemporary Western culture does not justify the need for a new methodology. Indeed, it is still important to take into account a genealogical approach to visual culture, one which challenges the presentism effected by the endless cycles of regeneration and renewal prompted by academic audit processes. Scholars who are skeptical of the historical abilities of visual studies have dismissed it as a mere disciplinary innovation that deals with popular illustrations, new media, artifacts, and design.

However, visual culture is not oblivious to the historical problems about vision. The very term 'visual turn' should be taken to task, for it invites us to explore the multiple directionality of turning around and turning to what calls for our attention in order to overturn what we perceive to be a problem in visual culture. Feminist theory has a crucial role in asking historical questions, which turn upside down the patriarchal separation between sexuality and regimes of visibility, particularly in the colonial/postcolonial arena. Mirzoeff acknowledged "the continuingly dynamic force of feminism (taken in the broad sense to incorporate gender and sexuality studies) to challenge disciplinarity of all kinds" (2003). The role of feminist visual theory is particularly significant to challenging the way in which sex, gender, race, ethnicity, and class are exchanged in culture as differences, which are historically constituted and institutionalized, especially in relation to a critique of the White privilege of the Western academic discourse (Pollock, 2003). In her account of the historical construction of oppositional Black spectatorship, bell hooks notoriously confronted the fact that many feminist film theorists were unable to see how race informed their looking relations. Hence, she discussed how the Black female spectator has to develop a position which is neither that of 'woman as image', nor that of 'man as bearer of the look' in order to create another space of identification, that is oppositional. "Looking at films with an oppositional gaze, black women were able to critically assess the cinema's construction of white womanhood as object of the phallocentric gaze and choose not to identify with either the victim or the perpetrator" (Hooks, 1992).

Irit Rogoff has argued that the political project of visual culture is deeply historical, for it revisions conventional narratives by showing that the difference between whom we see and whom we do not see is linked to the difference between 'aspects of the historical past', which have been given circulation, and some which have not (2003). Why do some images become intelligible, and why have others remained unintelligible for a long time? These questions do not enter the field of the humanities and social sciences with the visual turn but are already embedded in the agenda of critical theory. Walter Benjamin had already reflected on the readability of images in relation to historical materialism. He suggested that the readability of history is inscribed in its concrete, immanent, and material visibility, a form of 'graphicness' (*Anschaulichkeit*) that allows us to 'break with vulgar historical naturalism' (Benjamin, 1999). Benjamin's position lays bare a distinction between seeing and knowing that ought to be constantly interrogated. Within history writing, this entails a consideration of visual documents not simply as an illustration of a fact, but as a historiographical tool to mobilize the story told (or untold) by archival sources.

Interdisciplinarity, Transdisciplinarity, Indiscipline

The emergence of visual studies also responds to a cross-disciplinary definition of 'theory', not as a prescription of methods of interpretation but as a reflexive analysis of the discourses through which texts and meanings are interlinked (Culler, 1988). However, as the etymology seems to suggest (from the Greek *theōria*, meaning 'a sight', 'a spectacle', 'a form of viewing'), theory too is to be turned, for it is part and parcel of the structures by which seeing is regulated. What the English-speaking academia calls 'theory' in the globalized arena is not only intrinsically bound up with the supremacy of visuality in the Western epistemological tradition, as extensively discussed by Michel Foucault, but also inextricably intertwined with power relations, fantasies of mastery, surveillance, and containment that inform the very possibility to represent difference.

Thus, the visual turn presents itself as a metatheoretical question, and too often it has been dismissed as an exquisitely academic issue. Regular debates around the alleged usefulness of certain methodologies have tinted the visual turn with a polemical tone that responds to the perceived overlapping of

scholarly interests, particularly with regard to traditional academic disciplines such as art history, anthropology, literature, and sociology. Many scholars identify the visual turn with postdisciplinary academia, and this has triggered the dissemination of a number of different, if not contrasting definitions. According to Mieke Bal, the concept of transdisciplinarity presupposes an "immutable rigidity, a travelling without changing", while multidisciplinarity would be to "subject the fields of the two disciplines to a common analytic tool". She does not consider either of these options as viable ones and thus wishes for a 'travelling' theorization of concepts across the humanities and social sciences, one which is open to continuous negotiations, transformations, and reassessments (2002). Mitchell has put forward the idea that visual culture may even be defined as an 'indiscipline' (2002), for it develops a 'parasitical approach' that questions and critiques the material ways in which singular disciplinary subjects employ images and objects to create, contain, or enable different viewing positions.

Such suggestions have triggered some defensiveness on why and how academic disciplines might need new terms. In confronting directly these disciplinary anxieties voiced in the October questionnaire of 1996, Svetlana Alpers reminded that "Disciplinary boundaries, like differences between artistic mediums, are a subject of investigation, not of denial" (Alpers, 1996). This still seems a relevant advice to overcome the fear of theoretical catachresis, and it is also an invitation to foster a critical examination of the cultural layers that enfold the practice of looking within and outside academia. The need for a new theoretical posture proposed by the visual turn is not justified by a fancy for innovation, but derives from the institutional and historical awareness that "we cannot ask the new questions in the old language" (Rogoff, 2003).

Beyond the Word/Image Opposition

In an iconographical compendium of the seventeenth century, made for the use of artists and scholars, Cesare Ripa says that images are made to signify something different from what can be seen. This early modern claim can be taken to signal a semiotic attitude that, in part, may still be valid for those who analyze pictures like units of language comprising of signs, symbols, icons, and attributes whose connection produces meaning. The import of linguistic models to analyze visual objects is not a recent one. The genealogy of visual studies can be traced back to the rhetorical dispute about the supremacy of words over pictures. The ancient topic of ekphrastic literature, for instance, or the poetics of paragone have informed the very inception of iconology as a study of the image in modern times, and still represent a spur for scholarship in visual semiotics and intersemiotic translation (Mitchell, 1986; Bal and Bryson, 1991). Unlike linguistics concerned with the quantifying of the intersemiotic translation between words and images studied within a circumscribed context of signification (Groupe μ, 1992), visual studies pay particular attention also to the way in which visual signs may exceed systems of representation, moving across different sensoria, affects, materialities, and media (Schefer, 1995). Unlike visual hermeneutics or traditional iconology in which historical agents are represented as responding to specific cultural contexts, visual studies reintroduces the subjectivity of the analyst that the iconologist had evacuated, in order to show how meaning is rhetorically produced and reproduced through history, rather than frozen in a single moment of the past (Holly, 1996).

Visuality and Textuality

Following Jacques Derrida's dictum that "there is nothing outside the text", visual studies turn down the separation between objects of analysis (text/images) and contexts (social or historical background, biography, institutional spaces) sustained by historicist and psychologizing methods of interpretation that champion the concept of intentionality. Moreover, it has taken from semiotics the antirealist tenet that visual culture is made of signs that stand for something other than themselves and are always in relation to each other. This approach erodes the illustrative function of the image, thus liberating tasks and potentials that are charged with political significance. Consequentially, some have attacked visual studies for having undermined the historical function of images. Yet, it is precisely in the critique of the naturalized match between what can be said of what we see that the historical project of visual studies must be found.

Visual studies reflect on the problematic permutability between verbal and pictorial utterances. The interest in analyzing modes of presentation and representation is notably subsumed from structuralist linguistics. Early visual theorist such as Meyer Schapiro, Hubert Damisch, and Louis Marin have in fact looked at semiotics and linguistics to examine pictures as significant units structured like a language with a specific visual grammar and stressed the ability of images to perform acts of enunciation. Mieke Bal and Norman Bryson have argued that certain dematerialized linguistic categories, such as the pronoun 'I' and its coterminous 'you', but also adverbs like 'there' or 'today' have no referential value: they do not stand for a real person, object, place, or time external to the system of representation. Instead, their value is relational and internal to discourse itself (1991). These are 'deictic' terms that define the subject of discourse visually, while marking the possible not correspondence between speaker and subject. The insistence on the contiguity between 'I' and the 'eye' in a picture, for instance, is based only on the assumption that the subject may always have the power to be the one who looks. Here there is a question about the relationship between knowing and seeing that informs a number of poststructuralist methodologies, most notably feminist, women's, and gender studies, which critique the disparity between look and sight, i.e., looking and being looked at. For instance, in Édouard Manet's famous painting of *Olympia*, first exhibited in 1865, her look is actively fixed outside the painting, and this challenges the objectification of looking: the viewer is no longer the 'I' who can take possession of the woman, for Olympia's look positions him as a 'you' who is accountable for his act of looking. The notions of gaze, look, voyeurism, scopophilia, and fetishization devised by feminist visual theories in the 1970s have instigated a revision of the narrative strategies and technological supports that keep certain mystifications of gender in place within the field of art history, media, and film studies (Pollock, 2003). The possibility of mobilizing subject positions within a picture is precisely the signal that the codes

of visuality are not naturally fixed, but inherently constructed through gender.

Envisioning the Linguistic Turn

The intersection between semiotics, linguistics, and visual studies goes beyond a mere borrowing of theoretical jargon, for it is embedded in the very conceptualization of the turn. In fact, the phrase 'visual turn' has gained popularity by its assonance to other postmodern turns within the humanities and social sciences, most notably the 'linguistic turn'. The linguistic turn, which in the humanities and social sciences is often associated with a shift from structuralist to poststructuralist semiotics, bears the proposition that language constitutes reality and that the linguistic model ought to be the model for all communications. While metaphysical thinking takes language as a label that is tagged to concepts and objects, thinkers like Jacques Derrida and Michel Foucault borrowed from Ferdinand de Saussure's structuralist linguistics the idea that the relationship between signified and signifier is arbitrary. Thus, the linguistic turn is particularly interested in the metaanalysis of the linguistic tropes and narratives that convey truth and believability as such.

There are two key issues that arguably made the linguistic turn attractive for what here is being termed as the visual turn. The first has to do with the fact that, by shifting our attention from an abstract conception of text to a material source of textualities, the linguistic turn emphasized the unacknowledged role of writing as discourses in which the subject is inscribed. The emphasis on discourse is grounded on the idea that the speaker is not the subject of language, but the speaker exists as long as he or she is subjected to language. Thus, language and symbolic systems in general are not an expression of subjectivity, but rather they represent the agency that produces subjectivity by projecting around the speaker the space of the subject (Benveniste, 1971[1958]). Michel Foucault, who referred to this process as *assujettissement*, defined discourse as a body of knowledge that both defines and delimits what can be said about something. Discourses obviously change over time and are specific to certain social and historical contexts. As discourses regulate the administration of power and knowledge between the sayable and the seeable, there is no other way to visualize the subject but in intersection with discursive formations of identity and identification. Hence, visuality could be considered as the multifarious and fragmented discourse about vision, power, and knowledge.

Therefore, the second attractive aspect it follows is that the linguistic turn represents a break with the humanist conception of the subject, and challenged the idea that meaning should be traced back to the intentions of an agent or maker. Once it has been acknowledged that the meaning of a text cannot be tied up to a univocal source, but it has a life of its own, so to speak, it becomes easier to understand that the same might apply to images and visual culture that have in language their model of manifestation. For Derrida, the interpretation of a text or an image is enfolded within an irreducible and generative multiplicity of contexts and readings that he compared to 'dissemination'. Derrida proposes that meaning is a function of context, and that there are no limits or barriers to an endless sequence of recontextualizations. Hence, it follows that what dissemination displaces is the concept of an 'exhaustively determinable' context of meaning, that is a context originating in conscious intention (Derrida, 1982).

Frames and Contexts

The problematic of the context is a crucial one to establish a provisional distinction between the linguistic and the visual turn – at least, within the terms that have characterized certain academic debates. In fact, whereas scholars concerned with literary works have to join text and text, the visual turn has posed a new problem dealing with the translation between picture and commentary. Norman Bryson argues that within the historical disciplines, these elements traditionally stand to one another in a mimetic fashion, rather than in an analytical relation. The difference between text and context is conventionally established as "a separation that is at the same time an evident hierarchy, for the expectations that context will control the text" (Bryson, 1992). However, this separation also entails that, unlike the text, which still requires to be read textually, the context is often placed outside the text as an unquestionable propeller of meaning. Visual studies scholars have been extremely receptive to the claim, advanced within deconstruction philosophy and the linguistic turn, that the context does not partake with the purity of origins, nor is it a natural given, but it is something we make. If the context is produced by interpretative strategies, this means that contexts too are just as much in need of a critical analysis as texts are (Culler, 1988; Bal and Bryson, 1991; Bryson, 1992).

The context can be conceived visually, for it operates like a frame which, both and at the same time, encloses and displays its object. The frame is neither inside nor outside: it institutes the work. It is the frame, Derrida says, "gives raise to the work" (Derrida, 1987[1978]: 9). The frame oscillates between the two grounds that it constitutes – the work and the setting – and yet, with respect to each of these, it always dissolves into the other. The frame is all show and yet evades visibility; it is disavowed, yet already at work in fixing the look. One may think of a display within a museum. On the one hand, different framings encourage variable readings of the object, which are not necessarily related to its original function, and may even mystify its original meaning. On the other hand, a certain exhibition of the object can also expose ideas that were completely concealed in other forms of display or framing. This iterability of the sign illuminates the operations of dissemination in the field of cultural production.

Indeed, this is an issue that exceeds the museum walls, for the whole world is potentially contained into an exhibitionary paradigm under the powers of visual colonialism. Timothy Mitchell has convincingly examined the way in which anthropological exhibitions, a popular feature in world's fairs and international exhibitions, elicit the production of what he calls 'orientalist reality'. According to this principle, the Orient was defined as the product of unchanging racial and cultural essences, whose lack of progress was framed and exposed by the very exhibitionary paradigm that meticulously ordered races, costumes, and artifacts like specimens to put under scientific observation. However, the pretense objectivity flaunted by these systematic displays in fact betrayed a flawed image of the other as backward and primitive, thus providing

a visible and verifiable justification to the civilizing mission of Europe. As Timothy Mitchell puts it: "objectiveness was a matter not just of visual arrangement around a curious spectator, but of representation. What reduced the world to a system of objects was the way their careful organization enabled them to evoke some larger meaning, such as History or Empire or Progress" (1992).

The Biopolitics of the Visual

James Herbert stressed the tendency of visual studies to dematerialize what we see, in that "they shift the focus of analysis away from things seen toward the process of seeing" (Herbert, 2003). However, the alleged dematerialization in the methods of discourse analysis does not necessarily lead to the endorsement of a disembodied vision per se. In fact, the visual turn has also created a space to reflect on the effects of visual regimes upon the body. Take the representation of gender in general, and of femininity in particular. Griselda Pollock explains that, within the field of vision, women are looked at not because they are women: "I learn femininity – she says – as that repeated experience of being subjected to being looked at, appraised, accosted, commented upon and so on that will agonize my teenage years and cause older women to want their faces to be cut up in order to maintain the beautiful appearance" (2003). This first person account dramatizes what Teresa de Lauretis defines as "the power of discourses to 'do violence' to people, a violence which is material and physical, although produced by abstract and scientific discourses as well as discourses of the mass media" (quoted in Pollock, 2003). Culture inscribes on the body fixed meanings whose physical and material effects should be continually undermined if we want to establish new relations. Many feminist theorists turned to semiotics and psychoanalytic theory in order to question the association between the signifier 'woman' and concepts such as beauty, nature, and salability. Semiotics does not take the relationship between signifier and signified for granted, but takes that relationship precisely as an object of study.

The events of 11 September 2001 have represented a turning point for the discussion about the impact of institutional discourses upon corporeality. Mirzoeff argues that war is not only the subject of September 11, "but it is also a means of creating subjects" (2003). These events have reshaped the way in which we perceive the relationship between surveillance and safety, intimacy and publicness to a degree that has overstepped the mere domain of the visual and has invaded the whole sensory experience. In Foucault's terms, all bodies are shaped through biopower, that is institutional discourses which measure, define, identify, and categorize the body through political practices such as hygiene, birth control, health prevention, and beyond, including the broader fields of safety and security.

Our culture has become extremely saturated with images and devices that perpetuate the representation of violence and terror which trigger fantasies of previous horrors that have been traumatically interlocked with collective memory. Griselda Pollock and Max Silverman have borrowed from French poet and Buchenwald survivor David Rousset the phrase 'concentrationary universe' to define a system of total domination that annihilates the human in the concentration camp. Although condemnable, this system has somehow seeped into contemporary cultural imagination, particularly through forms of entertainment. Pollock and Silverman argue that the concentrationary is being replicated into novel and sometimes unexpected sites of visual experience: "via our spectacular identification as consumers of films, games and other cultural practices". These cultural objects often rely on processes of identification and misrecognition that "lure participant spectators into fantasies of mass destruction" (2013). The aestheticization of fascism in leather porn or video games like Manhunt 2 (2006), and the genetic paranoia conveyed in films like Children of Men (2006) represent only an unfinished archive of aesthetically different objects, whose politics of total domination continue to trigger a constant erosion of the human and its definitions.

Technological innovations constantly rewrite established visual theories, as in the case of the Foucauldian panopticon that has been reconceptualized across the intersection of sex and surveillance informing visualities on the Web. In reality shows, the live endears a compression of time and place that is reminiscent of classic scopic regimes like the peep show or the panopticon. However, Olivier Asselin has noted that the webcam instead subverts the parable of total surveillance epitomized by Foucault's theory of the panopticon, for this is not about one individual surveilling a group, but the other way around. Explicit representations of sex are rarely represented on live webcam shows; the webcam mainly broadcasts deserted interior spaces. Yet, sexuality is always there, as it is omnipresent, forever hoped for, forever suggested by the very architecturality of the medium (2008). Thus, the webcam can be considered as a pornographic medium not for what is represented, but for how representations operate by it.

Another important question deals with the way in which old visual technologies, like the cinema, deal with the representation of hitherto little seen sexual identities. In the past decade queer theory has been particularly receptive to the questions posed by the visual turn in order to overturn the relationship between identity and identification of non-heteronormative sexualities. Judith Halberstam has looked at the materiality of the cinematic medium to explain how the effacement of representations of the transgender body in the blockbuster movie *Boys Don't Cry* (1998) may be sustained by certain temporal and spatial axes embedded within the cinematic medium (what can be seen at what point in the plot of the movie). In this movie, the character of Brandon Teena passes as a boy, as long as no reference is shown to his past. Once transgenderism is exposed through the crude representation of a criminal episode of rural homophobia with lethal effects, Teena can only come back in the movie as a revenant that features in the guise of a ghostly voice from a police interrogation previously recorded. Halberstam writes: "When we 'see' the transgender character, then, we are actually seeing cinematic time's sleight hand. Visibility, under these circumstances, may be equated with jeopardy, danger and exposure, and it often becomes necessary for the transgender character to disappear in order to remain visible" (Halberstam, 2005).

This issue raises a question of how visual studies approach invisibility as a problem lying within, and not outside the field of representation. In recent phenomenological debates often

referred to as 'the affective turn', the body has become a pivotal standpoint from which to ground political and social questions. In this sense, the representation of corporeality and sensorial experience is not lost in discourse or language, but it is continually rematerialized in a number of contexts that demonstrate how much the invisible matters to the social production of fantasies, fears, and anxieties that have the body as the first object and objective. One should think of the cultural perceptions of HIV/AIDS which created a number of cosmetic visualizations within popular visual culture as a means to cope with the spread of fears about touch, contagion, and the skin; or also the spectacularization of sonograms in the public arena, which has material effects upon women's health in the context of abortion and self-determination (Cartwright and Sturken, 2001).

French philosopher Jacques Rancière has recently rebooted the political agenda of the visual turn by putting an emphasis on the way in which regimes of visuality intervene within what he calls the 'distribution of the sensible' (*partage du sensible*). Distribution here refers to both forms of inclusion and exclusion of what can be apprehended by the senses: what can be said of what we see, what can be heard of what is said, what is made visible by what we say, etc. Rancière comes to this proposition from an elaboration on the aesthetic regime of art and critiques the way in which a certain distribution of the sensible might endorse forms of consensus about, e.g., what can be said of what we see, rather than fostering creative forms of 'dissensus' that make democracy possible (2009). It is perhaps in this possibility for disagreement that the pedagogical position of visual studies may ultimately lie, in between self-reflexivity and self-critique, if they really are about enabling emancipation, rather than simply delivering another form of training.

Re-Turning the Visual Turn

Nicholas Mirzoeff has defined visual culture as a "tactic with which to study the genealogy and functions of today's life from the point of view of the consumer" (1999). Such statement does not necessarily bind visual culture to the analysis of contemporary design, video games, or advertisement, since also the past should be studied as a commodified projection, which comes in the shape of coffee table books, blockbuster exhibitions, and cruises to heritage sites. Yet, his statement could also be turned against the visual turn itself, for that too is imbricated in the profitable circulation of knowledge promoted within globalized academia. A possible way to interrogate this issue could emerge from a reflection on the generations and temporalities of the visual turn, that is an analysis of the rhetorical strategies and chronological narratives through which visual studies have been discussed and indeed presented as a turn.

A survey of the many voices that have partaken in such debates has shown that the history of the visual turn is often told through a narrative of progress, success, and overcoming. The old guardians of aesthetic value, experts, and connoisseurs, have been supplanted by analysts whose methodological and theoretical concerns are presented as more sophisticated, discursive, democratic, inclusive, etc. Yet, beside this account of emancipation lies a modernist fantasy of identity that eschews a confrontation with the effects of the postdisciplinary commodification of 'theory'. Shifts or turns not only highlight an epistemological direction, but also a temporal one. Clare Hemmings has argued that the narrative of progress is a textual technique describing a trajectory from sameness to difference, singularity to multiplicity, simplicity to complexity. Yet, progress narratives are also intertwined with narratives of loss: they claim that the past is over, and in one single move they want to make the new more attractive and, therefore, more salable. Of course, this is not specific to the visual turn (in fact, Hemmings here is talking about feminist theory), but this may initially help us to disentangle and break down its 'political grammar' (2011).

Take the impact of the visual turn on art history. It has been said that visual studies is not 'a discipline' that has stretched the art historians' interests in order to accommodate new media (photography, video, the press); neither is it a mere methodological updating. Visual studies rightly stress the fact that vision itself is already a form of critique that enables us to rewrite culture. This position has been welcomed among art historians interested in upsetting conservative aesthetic values by mingling disparate objects in order to reshuffle historiographical periodizations, which maintained low and high culture apart. Irit Rogoff has fostered the impact of visual culture upon art history for bringing forward a cultural awareness about vision that has made it possible to shift from the 'good eye' to 'the curious eye' so that issues like desire, corporeality, sexuality can now be treated historically (2003). This is a vital shift, and should not be undermined. Still, we owe to ask what happened to the old values, which used to be defined by the 'good eye', and whether they have been lost, or rather they have been transposed onto other spheres of public life. It is equally vital to ask whether the more attractive term 'free choice' may have become the new word for the outmoded normative concept of 'taste'.

Martin Jay urged that an indiscriminate leveling of visual culture could make us lose the "ability to make distinctions among different kinds of images and experiences". He also suggested, "traditional art history with its canonical restrictions still has a lot to teach us about the ways in which optical virtuosi, those with the gift of training to explore and extend the limits of the visual experience, transcend the conventions of their visual environment and open up new worlds for our eyes" (2002). In a similar vein, Thomas Crow already pointed out, "to surrender a history of art to a history of images will indeed mean a de-skilling of interpretation" for a whole generation of scholars (1996) and, it should be added, the expendable re-skilling of the younger one. With reference to this statement, Mitchell concluded, "the erosion of the forensic skills of connoisseurship and authentication among art historians in favour of a generalised iconological interpretative expertise is a trade-off that ought to trouble us" (Mitchell, 2002: 168).

Perhaps, it is due to that de-skilling that today we can see a whole new generation of scholars whose theoretical plasticity becomes all the more attractive the lesser it is resilient to the fluctuations and demands of the academic and publishing markets. All these considerations should be assessed in their own terms. No one is calling for a return to connoisseurship or elitist aesthetic values. Nonetheless, embracing new skills or

losing old ones appear as mutually exclusive options only until they remain fastened to a narrative of progress, that is also a story of consumption. These considerations, then, pose a question that becomes the more urgent the more we lose our ability to counter the argument that the value of the arts should be calculated only according to profitable terms. Visual culture appears to us only as the reified memorabilia that have often been buried without even entering the realm of political experience. Instead, one should not underestimate the powers of the outmoded in triggering unrealized theoretical imaginaries. Indeed, if we are to embrace a narrative of progress in the visual turn, one must also sustain a narrative of return to old questions. It would be very idle to be contented with fostering theoretical progress by simply disseminating methodological amnesia.

Abstract

Together with eye movement control, visual word recognition is the fundamental process underlying reading performance, but while the former is natural and basically innate, word recognition is highly artificial and usually takes years to learn. Neurocognitive psychologist use a variety of methods and models to investigate how humans (learn to) perform the multiple subprocesses underlying word recognition, for example, discriminating and recognizing the written equivalents of elementary speech sounds (phonemes), or automatically constructing the meaning(s) of a word. Modern neuroimaging research suggests that word recognition is a nonlinear dynamic, embodied process temporally distributed over several hundred milliseconds and neuroanatomically distributed across a range of cortical and subcortical networks, questioning the classical notion of a passive retrieval of word knowledge from a hypothetical mental lexicon. In a world full of illiterates and dyslexics, the biggest challenge for neurocognitive psychology is to provide the applied disciplines with the necessary and sufficient knowledge making it possible to design efficient and reliable methods for diagnosis, teaching, training, and rehabilitation of visual word recognition and reading.

Reading is one of the greatest achievements of both human civilization and the human mind. It is based on two fundamental processes: word recognition and eye movement control. While eye movement control is a natural, basically innate process – we move our eyes naturally about three to four times per second across sections of the environment to bring objects into focus – visual word recognition is not natural, but a highly artificial activity of the mind that comes at a cost: for most people it takes years to learn it. Unlike native speech and auditory word recognition which are acquired more naturally, children have to learn visual word recognition as much as adults who study a new language, and possibly, even a new script.

The neurocognitive psychology of visual word recognition investigates the mental and neuronal processes that allow readers to map printed symbols onto sounds and meanings and those that allow readers to become amazingly skilled in this highly complex activity. It uses a variety of neurocognitive methods (e.g., psychophysics, mental chronometry, brain imaging, and stimulation techniques) and models (e.g., boxological, mathematical, and computational; for a classification see Jacobs and Grainger, 1994) to explain how humans (learn to) perform the fundamental subprocesses underlying word recognition: (1) discriminate and recognize the written equivalents of elementary speech sounds (phonemes), that is, letters/graphemes (in alphabetic scripts) from the environment, for example, a text; (2) transform information about those symbols (e.g., phoneme/letter identities and their relative position) into information about sound and meaning.

Major Issues

Most of the neurocognitive research on visual word recognition studies the question how humans can gain rapid and automatic access to the meanings of single words. Other major issues concern: (1) how beginning readers learn and apply the alphabetic principle in perception and action; that is, the mapping of letters (or letter groups) onto elementary speech sounds, which allows them to 'decode' the thousands of spoken words that are in their mental lexicon prior to reading; (2) the functional units of learning/processing written words (e.g., letters/graphemes, phonemes, syllables, or morphemes) and their neural correlates; (3) the question as to which role orthographic, phonological, and morphological processes play in learning to recognize and process visual words and the temporospatial dynamics of these processes in the brain; (4) the neural and behavioral causes and consequences of individual differences and deficits in the acquisition of literacy; and (5) the development of intervention methods to detect and remedy such deficits.

Learning Visual Words

Learning to read starts later than learning to speak, for most people around the age of 5 or 6 years. During several years thereafter children must acquire the code used by their culture for representing speech (sounds) as a series of visual symbols, that is, mapping letters (orthography) onto phonemes (phonology) and vice versa. In most languages, the relationship between symbol and sound is systematic, whereas the relationship between symbol and meaning is largely arbitrary. According to one influential model (Frith, 1986), learning to read words is not gradual, but progresses in steps. When the letters of the alphabet have been learned, in step 1 the child applies a logographic strategy; that is, instant word recognition on the basis of salient graphic features, such as the oval around the sign ESSO. In step 2, the alphabetic strategy is applied, that is, a strictly sequential blending of sounds to evoke a word, such as cuh-a-tuh which English-speaking children often use to

read CAT. In step 3, finally, the orthographic strategy is applied, that is, instant word recognition on the basis of orthographic, syllabic, or morphemic cues.

Another important theory of reading development assumes that children rely on phonological decoding skills to learn novel words (Share, 1995). According to this theory, every successfully decoded word provides the child with an opportunity to set up direct connections between a given letter string (orthography) and the spoken word, which results in the development of an orthographic lexicon. Phonological decoding thus provides a powerful self-teaching device because the explicit learning of a small set of spelling–sound correspondences allows the child to decode an increasingly large number of words, which bootstraps orthographic and lexical development (for an implementation of this theory, see Ziegler et al., 2014).

Learning to read words correctly is made difficult by a number of learning/processing problems that differ across alphabetic languages (Ziegler and Goswami, 2005). The *availability problem* reflects the fact that not all phonological units are consciously (explicitly) accessible prior to reading. Thus, connecting letters to phonemes that are not yet readily available requires further cognitive development. The *consistency problem* reflects the fact that identical visual units can represent different sounds and vice versa, as illustrated in the famous "Beware of HEARD a dreadful WORD, it looks like BEARD and sounds like BIRD … ." Finally, the *granularity problem* reflects the fact that there are many more orthographic units to learn when access to the phonological system is based on bigger grain sizes as opposed to smaller grain sizes, like in English. That is, there are more words than there are syllables, more syllables than there are rimes, more rimes than there are graphemes, and more graphemes than there are letters. A related problem is that higher-level representations are more accessible than lower-level ones. Thus, English-speaking kindergarteners have better access to the number of syllables in a word than to the number of phonemes in a syllable. They also have better access to rimes than to phonemes. A further problem is the dominance of meaning over form. An example is the observation that common semantic features of two words (e.g., the fact that TIGER and CLOWN are associated with a circus can mask phonological differences between them (e.g., that TIGER and CLOWN have different onsets). An example which should be familiar to all adult readers is that one has better mnestic access to semantic features than to form features (e.g., upper- vs lowercase) of words (cf Jacobs, 2001).

As concerns the problem of gaining access to meaning of written words, the debate revolves around two alternatives: (1) skilled readers access meaning through phonological recoding of written words (i.e., the translation of visual units into sound codes in reading) (Van Orden, 1987) or (2) they access meaning directly from orthography without phonological mediation (Coltheart et al., 1993). Current computational theories agree that both pathways are used during skilled reading (Coltheart et al., 2001; Perry et al., 2007) and the weight given to either of them might depend on factors such as the orthographic transparency of the writing system or the proficiency of the reader (see Section Meaning Construction in Context). A related open question is whether orthographic and phonological processes are interactive or independent, and whether they develop interactively or sequentially. Many studies suggest that written words automatically activate their sound representations and there is increasing evidence for strong bidirectional interactions between orthographic and phonological processes even in skilled adult readers (Ziegler et al., 1997).

Which visual units are functional in learning and processing words? The majority of studies suggest that reading is letter based (e.g., Nazir et al., 1998), but intermediate units, such as phonemes and graphemes (Rey et al., 1998, 2000), vowel–letter clusters (Chetail and Content, 2013), syllables, and bigrams (Conrad et al., 2009, 2010) or morphemes (Rastle et al., 2004) have been found to play a role in going from letter representations to whole words. Proficient readers thus seem to make use of any kind of helpful information that efficiently and reliably leads to the disambiguation of a word in a given context (see Section Processing Visual Words).

How is the recent cultural invention of 'words' (<6000 years) constructed in the human brain? Since evolution hardly had time to develop inbuilt mechanisms for word recognition and reading, learning to read must involve a preemption of parts of the existing visual system and its conversion, by minimal modification, to process the shapes of letters and words. Indeed, in most expert readers, a localized region of the left occipito-temporal sulcus, just lateral to the fusiform gyrus, systematically takes on the function of identifying visual letter strings. This 'visual word form area' is thought to play a pivotal role in informing other temporal, parietal, and frontal areas of the identity of the letter string, for the purpose of both semantic access and phonological retrieval (Dehaene et al., 2005).

Processing Visual Words

For many decades the prevailing theory on word recognition was that word representations are stored in a mental lexicon which is a part of long-term memory and from which the grammar processor retrieves them to understand phrases and sentences. More recent approaches favor an alternative view; according to which, words are objects, that is, sensory stimuli that act directly on mental states, meaning, they are active operators rather than passive operands, and rather than having a fixed meaning, they are 'cues to meaning,' which means, their meaning lies in the context-dependent causal effects they have on mental states (Elman, 2004). The view that words are objects, and thus are coded via their sensory–motor features, that is, primarily the sound–image and articulatory program, goes back to early neurologists/aphasiologists like Freud (1891) and language theoreticians like Bühler (1934), who also anticipated recent 'embodied cognition' theories of word recognition, according to which the meaning of words is grounded in the sensory–motor activities of the objects/actions/events they refer to (see Section Meaning Construction in Context).

Modern neuroimaging techniques, such as magnetoencephalography (MEG) and functional magnetic resonance imaging (fMRI) provide interesting insights into how the brain processes written words, showing that this process is far from being as instantaneous as the subjective intuition of an adult reader – who can read 250 words per minute without being

aware of the fact that fully recognizing each word might take from one-fourth to half a second – might suggest. Even highly automatized word recognition in skilled readers is thus a process distributed over time with a variable time course depending on many context factors, such as word familiarity, orthographic, phonological, morpho-syntactic or semantic complexity, or reading skill. When a printed or written object (i.e., a word) is projected onto the retina, areas in both occipital lobes (e.g., V1 to V4, occipito-temporal sulcus) start to extract visual features like strokes, angles, curves, or contours from the object and synthesize them into letter shapes. Already after one-tenth of a second, the above-mentioned 'visual word form area' in the fusiform gyrus of the left hemisphere has helped to construct a preconscious word representation from these features and letters. For this neuronal representation to become consciously available, it needs to be coupled with the corresponding sound representation, taking about another one-tenth of a second of processing, mainly in areas specialized for speech in the left temporal lobe. About another one-tenth of a second is then taken up by activity in neural networks of the left frontal cortex related to constructing the context-dependent meaning of the word. All these activities largely develop not only in parallel and in a distributed fashion involving large parts of the left cortex, but also as bilateral subcortical structures of the limbic system, or the cerebellum, as well as some right-hemispheric areas in order to construct the full meaning of a word, including simple affective features, such as 'pleasant' or 'disgusting,' morpho-syntactic features like case role, or semantic features like 'human' (Citron, 2012; Conrad et al., 2011; Hofmann et al., 2009, 2011; Kuchinke et al., 2005; Ponz et al., 2013; Recio et al., 2014; Vosse and Kempen, 2009).

Meaning Construction in Context

Studies on single word recognition, that is, processing words in isolation, can only reveal limited insights on how the ultimate goal of reading is achieved: making meaning out of a series of written symbols. The widely spread idea that readers decode words by decomposing them into semantic 'atoms,' thus leading to conscious access to their meaning independent of context, is not compatible with recent neurocognitive evidence. Many results suggest that the metaphor of a mental lexicon containing fixed literal meanings of words which are passively 'accessed' is a fallacy. Rather, during reading, the brain constructs several possible meanings of a given word (including figurative ones) in a context-sensitive, 'on-line' way – some aspects of meaning often being processed separately from others in different parts of the brain – as the result of nonlinear, dynamical interactions between bottom-up and top-down processes (Bazan, 2011; Elman, 2004; Forgacs et al., 2012; Jacobs, 2011, in press; McClelland et al., 1989; Schrott and Jacobs, 2011). These processes are much more complex than popular models of 'cold' information processing in reading (Just and Carpenter, 1980), word recognition (Coltheart et al., 2001), sentence comprehension (McClelland et al., 1989), or text processing (Kintsch, 1988) have proposed: it involves 'embodied' processing of sensory–motor and 'hot,' that is, affective or aesthetic, aspects and meaning construction processes such as the activation of context-sensitive frames/schemas, conceptual blending of information from different domains of reference or subject variables, such as ideas of reference or odd beliefs (Aryani et al., 2013; Bohrn et al., 2013; Briesemeister et al., 2011, 2014; Coulson, 2006; Jacobs, 2011, 2014; in press; Juhasz et al., 2011; Kutas, 2006; Nazir et al., 2008; Schrott and Jacobs, 2011; Siakaluk et al., 2008; Vo et al., 2006; Zwaan and Taylor, 2006).

Methods and Tasks

A wealth of (neuro-)cognitive methods (e.g., rating scales, mental chronometry, oculo- and pupillometry, electroencephalography (EEG), fMRI, transcranial magnetic stimulation (TMS), and near-infrared spectroscopy (NIRS)) allows to study the multiple processes involved in visual word recognition at different levels of processing (e.g., sensory–motor, mnestic, and affective) using a variety of dependent variables (e.g., subjective–experiential, neuronal, and behavioral) in a multitude of tasks (e.g., perceptual identification, silent reading, naming, lexical decision, and semantic decision). Research using these methods and tasks has identified a multitude of factors that influence visual word recognition, such as word frequency/familiarity, word length, lexicality, neighborhood density and frequency, imageability, concreteness, regularity/consistency, age of acquisition, emotional valence, figurativeness, or semantic cohesion (e.g., Balota et al., 2004). Some of these effects appear to be ubiquitous and independent of the task or the context, such as the word frequency effect; that is, the observation that familiar words are recognized faster than unfamiliar ones; others, such as the effects of emotional valence, appear to be more sensitive to context, task, or subject characteristics (e.g., Veltkamp et al., 2012).

In order to allow a synthesis of all the different effects observed in a multitude of tasks, it is necessary to develop a functional overlap modeling strategy identifying (with the help of computational modeling) the task- and context-independent core processes underlying visual word recognition (Grainger and Jacobs, 1996; Jacobs and Grainger, 1994). This also involves greater efforts at quantifying the relevant variables among the mass of factors mentioned above, for example, by replacing the subjective rating procedures used to 'operationalize' certain word features, such as imageability or emotional valence, by computational models allowing to quantify them in an objective manner (Westbury et al., 2014). This approach is valuable because it solves a long-standing methodological and epistemological problem of studies on word recognition and empirical psychology in general: the theoretically unwarranted use of dependent variables obtained in one study (i.e., ratings of imageability or valence) as independent variables in the factorial or other experimental design of another study. A final ambitious goal is to connect the cognitive and computational models in a meaningful way with both behavioral and neuroimaging data in order to distinguish between processes that are localized to specific brain structures (e.g., sensory–motor processing) and processes where specialization arises in the distributed pattern of activation over many different areas, each participating in

multiple functions (Hofmann and Jacobs, in press; Price, 2012; Taylor et al., 2012).

Models

As a rule of (neuro-)cognitive psychology, a given neurocognitive test should be accompanied by a falsifiable neurocognitive (process or task) model that makes explicit the processes and structures underlying performance in the test and allows to assess its validity, as well as qualitative and quantitative predictions about performance. Contemporary cognitive and computational models of visual word recognition can be distinguished according to about a dozen criteria (Jacobs and Grainger, 1994), such as pre-quantitative versus quantitative or learning versus performance models.

First, there are a number of abstract mathematical models that simulate word recognition as an optimal decision process that accumulates noisy evidence over time. While successfully capturing some aspects of the empirical data obtained in standard word recognition experiments (e.g., frequency effect in a lexical decision task), they are badly underdetermined with regard to the nature of the information driving optimal decisions (but see Dufau et al., 2012). These models thus simply fit the human data, and although they do so very accurately, they 'post-dict' existing results rather than predict novel results.

In contrast, algorithmically concrete models of the connectionist family, such as interactive activation models (e.g., Grainger and Jacobs, 1996; McClelland et al., 1989) are concerned with how specific word features activate specific orthographic, phonological, or semantic units through processes of interaction and competition (Hofmann et al., 2011). These models can not only simulate and predict a variety of standard behavioral word recognition effects, but also be meaningfully connected with neuroimaging data (Braun et al., 2006; Hofmann and Jacobs, in press).

Similarly, dual route models of reading aloud (e.g., Coltheart et al., 2001) also make the hypothetical mental processes that underlie word recognition transparent. They assume two pathways for going from print to sound; a 'direct' orthographic route that maps letters onto whole word units in an orthographic and phonological lexicon using interactive activation, and a sublexical route that maps graphemes onto phonemes. These routes operate at the same time and the results of their computations are integrated at the phoneme output level. While the sublexical route in earlier dual-route models (e.g., Coltheart et al., 2001) was serial, rule-based, and hardwired, recent dual-route models, namely the connectionist dual process model or CDP+, have replaced the rule-based sublexical route with a two-layer associative network that learns the mappings between graphemes and phonemes (Perry et al., 2007). This model has also been extended to process multi-syllabic words (Perry et al., 2010), which requires syllabic segmentation and sublexical stress assignment (see also Conrad et al., 2010) and to simulate reading development and developmental dyslexia (Ziegler et al., 2014). A notable advantage of this modeling approach is that it is already successfully used in guiding applications, in particular the diagnosis and treatment of dyslexia (Engl et al., 2013; Ziegler et al., 2008).

Applications

Basic research on visual word recognition and reading development has been tremendously important for our understanding of how reading should be taught (for review, see Rayner et al., 2001) and how reading disorders, such as acquired or developmental dyslexia, should be diagnosed and treated (e.g., Engl et al., 2013; Heine et al., 2012; Thaler et al., 2009). With regard to the former, it is today well established that (1) mastering the alphabetic principle (that written symbols are associated with phonemes) is essential to becoming a proficient reader in all languages (Ziegler et al., 2010) and (2) methods that teach this principle directly are more effective than those that do not (especially for children who are at risk for having difficulty learning to read). Thus, elementary school teachers who make the alphabetic principle explicit are most effective in helping their students become skilled, independent readers.

With regard to the diagnosis and treatment of developmental dyslexia, theories of reading development and skilled reading have become increasingly important in our understanding of how deficits in various subcomponents of the reading network can cause the kind of reading problems seen in children with dyslexia (Ziegler et al., 2008). It has become clear that the heterogeneity that is seen in the disorder can be directly related to the complexity of the reading task, which requires among others good visual and attentional skills, good phonological skills, and good spoken language skills (e.g., vocabulary). Although deficits in any of these basic components can cause dyslexia, it is important to note that phonological deficits tend to outweigh visual and/or orthographic deficits both in terms of the magnitude of the deficit and the number of affected children (Ziegler et al., 2008).

On the basis of research on skilled word recognition and reading development, a variety of reading interventions have been proposed that typically attempt to improve processing at one or several of the above-described levels. For example, computer programs that explicitly train the mapping between orthographic units and their corresponding sounds have been shown to be of help for training children with dyslexia in decoding skills(Engl et al., 2013; Kyle et al., 2013). Programs that train phonological awareness skills prior to reading or during the initial stages of reading have been shown to significantly improve reading (Ehri et al., 2001). Extra-wide letter spacing of text has been shown to improve reading accuracy and speed in children with dyslexia presumably by reducing the deleterious effects of crowding (Zorzi et al., 2012). A technique based on a rapidly moving window that unmasks the to-be-read text as children read along has also been shown to improve reading speed for children with dyslexia (Breznitz et al., 2013). This list is not exhaustive but shows the impact of fundamental research on word recognition for a better understanding and treatment of dyslexia.

Challenges

In a world full of illiterates and dyslexics, the biggest challenge for neurocognitive psychology surely remains to provide the

applied disciplines with the necessary and sufficient fundamental knowledge making it possible to design efficient and reliable methods for diagnosis, teaching, training, and rehabilitation of visual word recognition and reading. Given the enormous, heterogeneous set of models and methods in the neurocognitive literature, another challenge is theoretical and methodological unification. For example, fundamental research on eye movement control or speech perception still remains relatively disconnected from research on visual word recognition; research on implicit learning and working memory is still widely separated from research on reading. Also, more research on standards for model building and evaluation, as well as for evaluating diagnostic and teaching methods is needed, if we want to fully explain the conditions favoring optimal acquisition and mastering of reading. Finally, so far, too little effort has been spent on developing a more ecologically valid model of *literary* reading that not only takes into account the wealth of results that have been accumulated by studies on single word recognition and sentence comprehension – the vast majority of which used only very simple (i.e., monosyllabic and monomorphemic) words or simple, descriptive, nonliterary texts – but also considers the complex dynamics of emotional, immersive, reflective, or aesthetic processes that accompany reading of literary texts such as poems, short stories, or novels (Iser, 1976). A recent neurocognitive poetics model of literary reading that integrates elements of rhetoric, aesthetics, and cognitive poetics with neurolinguistic and psychonarratological concepts (Jacobs, 2011, 2014) makes first steps in this direction. First empirical support for this descriptive comprehensive model comes from studies on sentence and text processing, as well as poetry reception (Altmann et al., 2012; Bohrn et al., 2012, 2013; Hsu et al., in revision; Lehne et al., in revision; Lüdtke et al., 2014).

Visualization in Science and Technology

Michael Lynch, Cornell University, Ithaca, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Starting in the 1970s, historians and ethnographers of scientific practice began to treat images, inscriptions, and the technologies for producing them as centrally important aspects of science, rather than as secondary products of theoretical and experimental work. Visualization in science includes arrays of practices with instruments and tools that enable researchers to make phenomena visible and publicly available. Visualization is not limited to vision, nor is it limited to sensory perception, as it includes drawing, graphic recording, and other means of inscription on paper, and more recently projection on to screens. In many cases, phenomena of interest to researchers are rendered into visible and palpable form only through such instrumental intervention and mediation. Different complexes of practice and instrumentation are associated with distinctive standards of objectivity modes of objectification. Images and models not only depict preexisting objects; but they sometimes have a proactive role in articulating configurations that only later are realized by imaging technology. Studies of visualization in science emphasize the links between different forms of data representation, and the labor process that develop and maintain the integrity of those links.

Scientific knowledge is represented in many forms: spoken and printed words, graphs, formulae, tables, drawings, engravings, diagrams, photographs, charts, maps, models, diorama, demonstrations, and many other more specialized renderings. Although linguistic propositions, measurable quantities, and mathematical formulae continue to be treated in philosophy of science as the primary bearers of scientific knowledge, historians, sociologists, anthropologists, and even a few philosophers have grown accustomed to treating images, maps, sounds, and soundscapes as significant and irreducible tools and products in science. Moreover, the explosion of digital image processing in recent decades has drawn scholarly attention to the remarkable ease with which digital and digitized data are rendered into two- and three-dimensional images, animations, and models that combine and recombine multiple forms of graphic, pictorial, sensual, and verbal formats (Carusi et al., 2014; Coopmans et al., 2014).

Some of the most interesting work in science and technology studies (STS) examines complex relations among material, pictorial, and discursive constituents in scientific work. Often a scientific text, or even a single image, incorporates mathematical, verbal, and pictorial expressions in a single frame, so that cross-referential relations are at least as significant as the particular graphic forms and formats. Published tables and figures are just the tip of the iceberg, and illustration is but one of the many functions of visual images.

Three related senses of visual representation are important for current historical, literary, and ethnographic studies of science. A passive or static sense of the concept of representation refers to an image, inscription, or sign that depicts, signifies, or symbolizes something else. An active or dynamic sense of the word refers to the practice of *making* images and the action of *doing* representing; a sense that is closer to Ian Hacking's (1983) emphasis on how observation involves a practical *intervention* with the material things and fields observed. Yet another sense, developed in actor-network theory, plays off of the concept of political representation and applies it to the material domain in which an image, model, or prototype is a delegate that stands proxy for, and acts on behalf of, a nonpresent multitude (Latour, 1993). The term *visualization* often is preferred to representation, as it more specifically draws attention to the material practices and products of drawing, inscribing, engraving, graphing, mapping, amplifying, enhancing, and combining what is seen, heard, touched, or mechanically exposed and recorded. Research in the transdisciplinary field of sound studies (Thompson, 2004; Pinch and Bijsterveld, 2012; Sterne, 2012) has convincingly shown that scientific observation and technological intervention are not limited to visual apprehension and optical instrumentation. Observations, measurements, and demonstrations in many research fields often involve a kind of synesthesia in which sounds, vibrations, spectrographic patterns, nonvisible electromagnetic radiation are pictorially and graphically presented. However, such data almost invariably take visual form on paper (and, increasingly, on screens), even when the phenomena presented are not visual or optical.

Representing and Visualizing

The study of visual representation in science crystallizes lines of work from diverse academic disciplines. In the 1970s and early 1980s historians of science began to pay close attention to nonverbal representations and nonpropositional forms of reference (Rudwick, 1976), and at about the same time art historians took greater interest in the broad array of what Elkins (1999) has called "images that are not art": pictures and models that are crafted as products and by-products of scientific and medical work, but which are rarely considered as art (Edgerton, 1976, 1991; Alpers, 1983). Such scholarly attention to visual images, as material products of interest in their own right, motivated interest in the role of artisan skills, craft techniques, and visual technologies in the scientific revolution, and in the continuing place of visual arts and crafts in day-to-day laboratory work.

Visual Representation

Studies of visual representation in science include analyses of published and unpublished images, and of the historical crafts and technologies responsible for their production. Currently, there are numerous disciplinary and cross-disciplinary approaches to visual representation in the philosophy, history, and social study of science. Social, cultural, and literary studies of visual representation include a bewildering array of historicist, semiotic, feminist, cognitivist, epistemological, pragmatist, and other lines of interpretation. As many cultural and literary studies have emphasized, visual representations do not simply resemble natural objects: they express normative assumptions about the natural and cultural world; they incorporate historically and culturally specific artistic conventions; and they mediate political and cultural relations of patronage, commodity exchange, and subjugation. The active sense of the concept of representation points to a broad array of practices and technologies for making, producing, and shaping images and relations among images.

Visualization

Visualization means more than seeing or depicting, as it refers to the use of research tools and practices for uncovering hidden features, magnifying objects and enhancing analyzability, facilitating measurement and comparison, and making things, properties, relational configurations, and entire fields publically witnessable, intelligible, and accountable. Visualization includes efforts to convince as well as to exhibit. Consistent with a programmatic aim to investigate the content of natural science knowledge (Bloor, 1976), ethnographers, ethnomethodologists, and social historians closely examine the situated practices, inscription devices, and textual forms through which scientific data and pictorial representations are exhibited, analyzed, stabilized, objectified, and disseminated (Latour and Woolgar, 1986; Shapin and Schaffer, 2011[1985]; Lynch and Woolgar, 1990). These studies stress the significance of visualization as a crucial aspect of a continuing scientific revolution. This revolution involves the incessant invention, adaptation, and use of novel instrumental and literary technologies for revealing invisible objects, analyzing and demonstrating abstract relations, and disseminating knowledge.

Renaissance innovations in print and engraving technology, together with novel optical devices and artistic conventions, enabled natural philosophers to inscribe and reproduce faithful representations of observational experience (Ivins, 1969; Eisenstein, 1979). Latour (1990) uses the expression "immutable mobiles" to capture the dual sense of stability and mobility attributed to imprinted or engraved representations. Scientific matters of fact, while still controlled by those who had the means to purchase, build, and operate equipment like the telescope, microscope, and pneumatic air pump, were communicated widely through networks of coinvestigators, patrons, and other "virtual witnesses" (Shapin, 1984). In most cases, virtual witnesses who read, for example, Robert Boyle's experimental reports were in no position to replicate the original experiments, but Boyle's detailed descriptions illustrated by engravings of observed phenomena and laboratory instruments stood proxy for hands-on experience. The literary technology of virtual witnessing enabled Boyle to disseminate experimental knowledge widely, while sparing all but a few well-equipped adepts from the difficulties and uncertainties involved in actually trying to replicate the experiments. The dissemination of printed and engraved representations facilitated, but did not guarantee, the stability (or immutability) of the knowledge in question, since printing, engraving, and publication compounded the contingencies of knowledge-production, enlarging the circle of potential disputants as well as adherents. The stability and mobility of images required a disciplining of the instruments and persons involved in their production and distribution. Instruments like the microscope and persons like engravers, printers, and publishers were subject to variable degrees of trust and distrust, and their activities became subject to legal institutions such as copyright (Johns, 1998). Consequently, whether located in a gradual historical process or in the temporal development of a particular laboratory or museum project (Knorr-Cetina and Amann, 1990; Star and Griesemer, 1989), 'immutable mobiles' depend upon continual efforts to control sources of distortion, disruption, and misinterpretation at every point of production and distribution.

Image, Object, and Objectivity

Numerous S&TS studies over the past four decades have examined the conceptual and interpretive practices associated with the production of visual images, and the communicative and community-building work associated with them. By elucidating the practical handiwork and collective labor process hidden behind the grand polarity of image and object, these studies challenge existing conceptions of the scientific image and its relationship to the natural world.

Studies of visualization address classic philosophical questions about the objectivity of reference and representation, but they give these questions an original twist. Instead of addressing these questions abstractly, S&TS researchers investigate specific cases in which scientists encounter practical dilemmas and devise provisional solutions. An ideal-typical version of such a dilemma is furnished by Hanson (1958: 4):

> Consider two microbiologists. They look at a prepared slide: When asked what they see, they may give different answers. One sees in the cell before him a cluster of foreign matter: it is an artifact, a coagulum resulting from inadequate staining techniques. This clot has no more to do with the cell, *in vivo*, than the scars left on it by the archaeologist's spade have to do with the original shape of some Grecian urn.

In this example, the observational instrument is both a material thing and a transparent medium through which other things appear. Depending upon what the microscopist sees on the slide, the instrument will be deemed a source of subjective deception or a means for revealing an objective cellular structure. One of Hanson's microscopists sees an artifact, but in the particular research context it is less like an artifact uncovered at an archaeological site (a Grecian urn) and

more like the unwanted traces on that artifact left by the spade that uncovered it. This example suggests that the distinction between objective structure and artifact can be contentious and difficult to resolve. In their restricted domain, the microscopists are faced with a standard philosophical question: "How do you know that the image stands for a real object?" Hanson argues that practitioners answer (or in many cases do not even raise) the question by relying upon their theoretical and experiential preconceptions about what can possibly exist in the domain under study. In his terms, they see the image as a theoretically possible entity or artifact. This conception of theory-laden perception denies that observational evidence is independent of interpretation, so that sensory evidence (aided by instruments) cannot unequivocally resolve deep theoretical disputes.

Like Hanson, Ian Hacking (1983) rejects any effort to treat representation in science in terms of passive observation, but, in contrast to Hanson's emphasis on the theoretical and conceptual background, Hacking points to the practical interventions performed with instruments. These interventions include cross-checks, calibrations, and probes that compare and contrast the outputs from different instruments and techniques. Convictions about reality inform, and develop from, a microscopist's competent handling of the laboratory instruments and materials. Hacking remains focused on the philosophical problem of how natural reality is validated, but he places the solution in the hands of the competent microscopist, aided by an arsenal of tools and instruments. The classical confrontation between subject and object is thus mediated (and sometimes obviated) by instruments and techniques. They are part of the means of perception, and like our eyes and our imaginations they sometimes are deemed as untrustworthy sources of subjective illusion. In microscopy and other laboratory sciences, correct judgment involves a mastery of technique as much as sharp eyes and an educated mind. A whole chain of preparatory actions precedes and sets up the dramatic confrontation between microscopist and cell. Cellular preparations are cultured, fixed, stained, counterstained, thin-sectioned, and mounted on a slide before they become visible (Lynch, 1985a). If the microscopist sees a foreign body – an artifact – in the cell, one or another of the preparatory techniques may be held responsible for the illusion. What the microscopist sees (or does not see) is thus bound up with a labor process that includes much more than looking down the tube of the microscope and focusing the eyes on an object.

When considered in light of the focus on instrumental praxis, visual representation (on paper, or on instrument screens) does not stand proxy for seeing with the eyes. Janet Vertesi (2014) suggests that "drawing-as" is a more adequate account of visualization than Hanson's interpretation of the Wittgensteinian theme of "seeing-as" (seeing a figure as something in particular, in line with the classic gestalt figure that can be seen alternatively as a duck or as a rabbit). The material media through which phenomena (including duck-rabbits) are inscribed on paper or projected on to screens are far from incidental features of observation. The philosophical question of how the mind relates to the world is not resolved on its own terms by reference to material graphic media; instead, it is transposed to a different space, where its resolution is provisional and practical.

Historicizing and Situating Objectivity

The concept of objectivity itself has been historicized in terms of artistic media and visualization technologies. Lorraine Daston and Peter Galison (1992, 2007) identify different eras of objectivity in the history of science. Objectivity, in their conception, is both a relationship of image to object and a historically situated moral ideal for apprehending that relationship. They identify these eras through an analysis of conventions used in illustrated atlases in various fields of natural history, science, and medicine starting in the sixteenth century and running through the present. The earliest era, "truth to nature" involved a commitment to the detailed rendering of the essential appearance and structure of natural phenomena. For example, a botanical specimen selected to illustrate its type, would be painted or sketched with great care to show characteristic details. Such careful depiction was attentive to, and productive of, representational standards designed to standardize the framing and perspective, and eliminate idiosyncratic variation. Renderings of this type can still be found in popular nature-study field guides (Law and Lynch, 1990), but Daston and Galison argue that "truth to nature" was succeeded (though not displaced entirely) in the nineteenth century by the moral ideal of "mechanical objectivity," in which mechanical reproduction of phenomena (through photography and other modes of imaging and data recording) was highlighted and artistic handiwork and interpretive intervention were actively discouraged (also see Porter, 1995). However, practitioners eventually realized that (suitably disciplined) judgment and (theoretically guided) imagination were necessary features of objectivity, because mechanical renderings could not by themselves stand as "images uncontaminated by interpretation" (Daston and Galison, 1992: 120), as they also were sources of noise, artifact, and other forms of deceptive appearance. Rather than keeping hands off of mechanical sources of data, contemporary scientists move among various instruments to configure fields of data and enable diverse forms of image production and analysis.

In their final chapter, Daston and Galison (2007: Chapter 7) suggest that a novel era of objectivity may be dawning in the twenty-first century, exemplified by the use of probe microscopes – instruments such as the scanning tunneling microscope (STM) and atomic force microscope (AFM). These instruments have been central to the coalescence of the multifield nanotechnology movement in science and engineering (Mody, 2011), and unlike optical instruments, they form topographic images at the nanoscale (a nanometer is one-billionth of a meter), analogous to the way a blind person sweeps a probe across a surface to feel the texture of a street or sidewalk and to detect any irregular features or obstacles lying in the path. Such instruments, according to Daston and Galison, afford haptic rather than optical apprehension, and the reality they access is 'presentational' rather than 'representational' – meaning that the properties of the object are inseparable from the operations of the instrument (as Prentice (2012) observes,

haptic apprehension has long been important for the practice of surgery).

Daston and Galison's provocative thesis effectively challenges the idea that objectivity is a static and coherent standard. Research on specific historical and contemporary cases of visualization supports much of what they argue, but it also complicates their narrative of a succession of eras characterized by the ascendency of particular moral/epistemological conceptions of objectivity. For example, Emma Frow's (2012) research on contemporary efforts by biology journal editors to police the use of digital image processing ('Photoshopping') indicates an unresolved tension that arises from technological possibilities that the editors hope to resolve with updated conceptions of truth to nature. The objective status of mechanical images also seems highly contextual in science and other fields, such as law. For example, while US courts in the nineteenth and early twentieth centuries were reluctant to treat photography and X-rays as self-sufficient forms of evidence (sufficient without supportive testimony by qualified witnesses), the popular (and, potentially, the legal) reception of brain scan evidence and DNA profile evidence seems much stronger and less critical (Golan, 2004; Dumit, 2004; Lynch et al., 2008). Such research suggests that, while notions of objectivity are historically situated, multiple versions of objectivity can be found at any given time in distinctive contexts of research, and that their relationship to one another is unlikely to fit into an orderly progression of eras.

Images and Models as Harbingers of Materialization

One of the most intriguing suggestions from studies of visualization is that images and models not only depict what scientists see with their instruments, they also have a proactive role in shaping how phenomena are visualized mechanically. Cambrosio et al. (1993) describe a controversy over diagrams that Paul Ehrlich drew at the turn of the twentieth century to illustrate his theory of the microbiological immune reaction. The diagrams included pictorial elements, but did not resemble any object that could be seen with microscopes or other instruments at the time. Instead, they were diagrammatic representations of hypothetical immunological entities (Cambrosio et al., 1993: 673; also see Kaiser, 2005 on Feynman diagrams). The ambiguity of the diagrams became a subject of controversy over whether their pictorial features presented viewers with a misleading "slippage from model to reality" (p. 684); a slippage from speculative chemical formulas to diagrams that included distinctive pictorial aspects reminiscent of cellular membrane configurations. To make a long story short, however, Ehrlich's pictures turned out to have heuristic value for materializing a novel entity – the antibody – and establishing the lock-and-key imagery that persist today in the field of immunology.

The idea that pictures, diagrams, and models not only stand proxy for observations but also are used proactively as materials for speculations, calculations, and tests of hypotheses is particularly clear in the fields of molecular biology and nanotechnology. The hand-held models, and later the animated computer models, used in molecular chemistry provide materials for puzzle-solving. In principle, the models incorporate structural features and combinatorial laws that act to constrain possible solutions, so that working with the models is akin to experimentation and measurement (Francoeur, 1997; de Chadarevian and Hopwood, 2004). Natasha Myers suggests that the image of subcellular "machinery" is more than a metaphor: it "embodies a 'fruitful collapse of metaphor and materiality'" (Myers, 2014; quoting Haraway, 1997: 97). Protein structures not only are depicted as though they fit together in gearbox-like assemblies, but they begin to look that way as imaging technology progressively reveals their structure.

The brief history of the nanotechnology movement also illustrates the idea of imaginary models and images as leading edges for mechanical visualization. K. Eric Drexler and the Foresight Institute were major promoters of nanotechnology in the 1980s. Many of Drexler's futuristic ideas about building functional and self-fashioning robots at the nanoscale were later dismissed as impossible, and the images of 'nanobots' (often depicted as though they were miniaturized submarines or space vehicles on voyages of discovery (Nerlich, 2008)) have been succeeded by more prosaic images of material surfaces and molecular constructions. Nanoscale phenomena are often said to be subject to quantum forces, and to differ profoundly from macroscale or even microscopic entities, and yet visual conventions for depicting clearly outlined, colorful, discretely positioned objects are abundantly used in both popular and professional depictions of nanoscale fields and objects. The translation of electronic current variations measured by a probe microscope into visual images of surface topography allows for a great deal of flexibility, and conventional models and images provide templates for resolving and visualizing such topography. Both serious and playful efforts to design molecules often configure them along the lines of cartoon figures and macroscopic machines and vehicles (humanoid stick-figures, nanocars and other nanovehicles) (Toumey, 2009; Ruivenkamp and Rip, 2010; de Ridder-Vignone and Lynch, 2012). Consequently, familiar things and artifacts provide imaginary templates for visualizing nanoscale entities and designing molecular machines.

Chains of Industry and Credibility

The STS treatment of visualization as temporal, embodied, material labor opens up a domain of investigation that is not covered by mentalistic and perceptual accounts of scientific observation. It ties in with a graphic and material, rather than cognitive or idealist, legacy, because the appearance of the scientific object is bound up with a temporal process, typically involving many hands in a division of labor. Marx famously credited Feuerbach with having stood Hegel on his feet, meaning that he placed Hegel's abstract dialectic on the firm footing of historical materialism. Less famously, Marx suggested a related way to bring history of science down to earth:

> … historiography pays regard to natural science only occasionally, as a factor of enlightenment and utility arising from individual great discoveries. But natural science has invaded and transformed human life all the more *practically* through the medium of industry; and has prepared human emancipation, however directly and much it has

> had to consummate dehumanization. *Industry* is the *actual*, historical relation of nature, and therefore of natural science, to man.
>
> Karl Marx, *Economic & Philosophic Manuscripts of 1844*.

A further inversion from feet to hands can be inspired by studies of visualization in science. For Marx, industry, rather than history of ideas, embodies the modern human relation to natural science. For STS, natural science is not simply the historical basis for modern industry and its relations of production. The laboratory's own labor process is itself a site of collective handiwork aided by instruments, with variable degrees of complexity, automation, and historical development. Marx speaks of the "working up" of raw materials into the form of a product; an artifact that embodies human purposes and provides a resumé of the labor process that produced it: "The product is after all but the summary of the activity of production." Among the products of laboratory work are data – carefully framed and emplotted observations and measurements which stand to nature much in the way that processed food does to raw ingredients. Scientists sometimes speak of raw data collected in the field or from electronic instruments, and they distinguish such data from processed images that result from 'working up' the data into presentable form.

Likening the visualization of a scientific data to a manufacturing process may seem to miss an essential point: that the object of scientific investigation is not an artifact, even though it may be difficult to establish the ultimate difference between natural and artificial features. In the vernacular of laboratory science, the object is found, not made (unless, of course, the scientist aims to file a patent claim), and it is distinguished both from deliberately constructed tools and inadvertently produced scratches, residues, and deformations. Close studies of day-to-day laboratory work have furnished many examples of how research materials are cultivated, handled, and reconfigured, but to conclude, for example, that all cellular structures are artifacts collapses a vernacular distinction that provides laboratory work with a fundamental task and tension. Such a conclusion also invites the sterile polarity and tiring polemics of the realist-constructivist debate. Latour tries to avoid the polemics by devising a neologism that straddles the polarity. According to Marx, the industrial product becomes a fetish – a commodity whose exchange value obscures the work of its production. According to Latour (1999: 272), the laboratory product becomes a 'factish' – a fact whose solidity and epistemic significance hides the day-to-day work of establishing and maintaining that solidity and significance. The 'factish' is never independent of its manufacture, but this does not reduce the fact to an empty screen for projecting arbitrary beliefs. The robust credibility of fact remains in place, not because it exists in an eternal space remote from human activity, but because of the way it is fashioned.

Latour's creative vocabulary is less instructive than his examples. In an ethnography of a Brazilian field project, Latour (1995) closely examined the series of practices through which a field site was made graphically analyzable. The project was concerned with a boundary between rainforest and savannah, and the question the researchers addressed was whether the trees were advancing into the grassland or gradually retreating. As scientific projects go, this one was simple. It involved only a few researchers, a down-to-earth problem, no complex equations, and relatively simple technology. Nevertheless, it involved a complicated series of representational practices: plotting out the field site into a systematic grid; selecting and tagging plant specimens; collecting and analyzing soil samples; plotting data on paper graphs; and endless record-keeping with multiple registers. The field site, the tagged specimens, the binned and color-coded soil samples, and countless other materials used in the project were hybrid objects. None of these things were purely natural or artificial, concrete or abstract, material or symbolic, real or imaginary, but a great deal of care was taken to preserve specimens, keep track of identities, and cross-check measurements and records. The project resulted in a publication in which a graphic figure represented the forest–savannah boundary, and the data collected during the project were used to support conjectures about the movement in question. Again, this was not a big or powerful project, and it resulted in tentative findings, but it served well enough to illustrate an important point about the credibility of the project's evidence. The researchers staked the credibility of their data on a complex network of accountability in which no single representation corresponded to an independent natural object, and yet all of them, in different ways, contained, encoded, traced, or preserved arguably natural properties of the field site. The credibility of the production was more like the strength of a rope, weaving together separate strands, and less like the compelling realism of a photographic image. Perhaps another example will help elucidate this point.

The police in the United States use the expression "chain of custody" to refer to the continuity of evidence as it is collected and transported from one place to another. So, for example, detectives and forensic pathologists collect blood samples at a crime scene, place them in tubes, and transport them to forensic labs, where they are analyzed with DNA profiling methods. Such evidence typically travels a complicated route, and it is transformed and repackaged several times in the process. Courtroom challenges have led the police to use a whole series of administrative procedures for checking, cross-checking, and validating the identity of evidence samples. Standardized forms, tamper-evident bags, stickers with bar codes on them, automated scanners, filing systems, and many other mundane bureaucratic artifacts create an administrative envelope that protects the credibility of evidence against challenge. The 'scientific' results of DNA profile analysis stand only as long as the administrative envelope resists challenge and no gaps are exposed in the chain of custody. None of the forms, bar codes, and protocols that make up the chain guarantee its integrity and continuity. Even an elaborately documented and impressively consistent chain of custody does not guarantee the truth of the evidential result against all possibility of error, mishap, fraud, and conspiracy, but when the numerical indices, signatures, and analytic results tell a consistent story, they are more likely than not to resist adversary challenge (Lynch et al., 2008).

It often seems natural to employ metaphors of vision, perception, and cognition when discussing scientific observation and representation, but the analogy with an industrial

labor process suggests a more material, and less ocular and mental, conception of visualization and its natural products. Consistent with the analogy with the assembly line, a scientific project is organized into a chain of tasks performed by a series of technicians. Specimen materials are collected, selected, prepared, rendered, and reorganized to expose, select, and mark relevant features, to upgrade analyzability, and to enframe data with instrumental and graphic fields (Knorr-Cetina, 1981; Lynch, 1985b; Goodwin, 1994; Latour, 1995).

Visualization thus includes the most fundamental relations between science and nature; it is not limited to pictorial images and illustrations. Studies of visualization take up epistemology's most basic topics – observation, representation, measurement, and objectivity – but in concrete, materially specific, situations of practice.

Abstract

Acquiring the words of one's language is, in principle, a challenging problem, but children solve it surprisingly easily. This article covers (1) the skills (speech perception, speech segmentation, and speech production) that children must acquire before producing their first words; (2) the main theories attempting to explain how the meaning of words is acquired; (3) the role of working memory in learning words; and (4) the acquisition of vocabulary beyond the early years. The tension between nativist and constructivist theories is discussed, as well as the challenges faced by future research.

Introduction

First words are typically produced between 10 and 18 months of age. Before reaching this stage, infants must acquire several competencies in phonemic perception, segmentation, and speech production. In spite of considerable empirical research and theoretical debate (mostly between nativist and constructivist researchers), we still do not know how children acquire vocabulary and language more generally. This article will consider, in order: (1) the skills that children must acquire before producing their first words; (2) how the meaning of words is acquired; (3) the role of working memory in learning words; and (4) the acquisition of vocabulary beyond the early years.

Acquiring Pre-Vocabulary Competencies

There is now good evidence that language acquisition starts before birth and that infants' perception of speech is affected by prenatal maternal speech. Three days after birth, infants already display a preference for familiar speech (Decasper and Spence, 1986). But there is still a long way to go before speech perception and production skills are sufficiently developed to enable the production of words. At the very least, before acquiring words, infants must develop three types of competencies: they must be able to perceive, segment, and produce speech.

Speech Perception

A phoneme can be defined as the smallest class of sounds that leads, in a specific language, to differences in meaning. For example, in English, /l/ and /r/ are two phonemes because replacing one with the other produces words with different meanings, as is apparent with '*r*oyal' and '*l*oyal.' (Note that phonemes are usually indicated by two slashes.) By contrast, /l/ and /r/ do not affect meaning in languages such as Japanese and Thai and thus are two instances of a single phoneme.

Infants face two sources of difficulty in finding out which phonemes to use (Rowland, 2014). First, the sound pattern of phonemes lacks acoustic invariance. Phonemes vary considerably in the way they are pronounced (the variations are called 'phones'): people speak with different accents, different speeds, and different pitches of voice (e.g., male vs female voices). In fact, it has been found that even a word as short and common as 'the' is pronounced in more than 50 distinct ways (Waldrop, 1988)! Another source of difficulty is that infants do not receive phonemes as an orderly sequence of sounds that are independent. On the contrary, these sounds overlap and interact – a phenomenon named *co-articulation*. For example, the phoneme /p/ is pronounced differently in 'my pet' and in 'your pet.'

Second, different sets of phonemes are used in different languages, as we have seen with the example of /l/ and /r/ above. It has been estimated that, in the world's languages, there are about 600 different consonants and about 200 different vowels. While most languages use from 20 to 37 phonemes (Maddieson, 1984), the problem faced by infants is to identify which phonemes are used in their language. Although the input obviously provides strong cues, this does not fully solve the problem because some groups of phones constitute a phoneme in some languages but not in others.

Segmentation

The speech signal is continuous and does not come with indications of where the words start and end. In this respect, it is different from many written languages that use spaces between words. Thus, one important and challenging task faced by infants is to segment speech into words – a task which is known as *word segmentation*. It is important to note that pauses in speech do not provide reliable cues to word boundaries, because pauses occur both between and within words.

Research has investigated the kind of cues that children might use to segment speech, and we briefly discuss the main candidates (see Ambridge and Lieven, 2011; Rowland, 2014; for a more detailed discussion). A first cue is provided by prosody, which concerns the rhythm, stress, and intonation of speech. Several languages have a characteristic stress pattern. For example, English has a trochaic pattern, where most words consist of a heavy stress followed by a light stress (e.g., language, infant). However, several languages do not offer a regular stress pattern (e.g., Inuktitut, an Inuit language of Canada, and French; Rowland, 2014), so this cue is not sufficient by itself.

We have mentioned earlier that the same phoneme can be pronounced with different variations (phones) depending on the surrounding phonemes and on the position within a word. Allophonic variation thus provides cues that can be used by infants for word segmentation. Another cue is offered by phonotactic regularities (i.e., the acceptable combinations of phonemes in a given language). Some combinations of sounds are not allowed within a word but could occur between words (or vice versa), and some combinations of sounds are more likely to occur at the beginning rather than the end of words (or vice versa). Thus, phonotactic cues can help segmentation.

Another source of information is provided by words that occur in isolation. Caregivers occasionally pronounce words that are clearly segmented. Using as criterion a gap of at least 300 ms in the speech stream after the preceding word and before the following word, Brent and Siskind (2001) found that 9% of the words met this criterion and were thus pronounced in isolation.

A final cue is provided by the transitional probabilities between words. Different syllables have a different probability of following a given word, and if infants learn even approximations to these probabilities, they can then use them as information to select the speech stream. That infants can do this, at least in an experimental situation, was shown by Saffran et al. (1996), who used a continuous sequence of nonsense syllables (e.g., bidakupadotigolabubidaku …).

Experiments have shown that infants can use the cues that we have reviewed; however, by themselves, these cues are not sufficient for successfully segmenting the speech stream. Ambridge and Lieven (2011) have therefore proposed that infants are likely to use multiple cues. In addition, infants gradually understand that speech conveys meaning and use meaning to isolate words.

Speech Production

While infants are precocious in perceiving speech sounds, production of the sounds of their language progresses only slowly. This is in part due to the immaturity of their vocal organs (e.g., the infant's larynx is located higher than the adult's, making it impossible to pronounce some sounds). It is generally admitted that speech production improves through a series of stages. Here we briefly describe the stages proposed by Vihman (1996) (note that the ages given are approximate).

In the first stage (*reflexive vocalization*, from 0 to 2 months), the sounds produced by infants include sounds expressing discomfort (e.g., crying), vegetative sounds (e.g., burping), and sounds related to physical activity (e.g., grunts). The second stage (*cooing and laughter*, from 2 to 4 months) is characterized by the appearance of comfort sounds, which normally occur when other people smile and talk. The third stage (*vocal play*, from 4 to 7 months) is characterized by vocal play sounds (e.g., squeals), which are made possible by the maturation and better control of articulation. This stage also sees the beginning of primitive babbling, with sounds starting to resemble consonants and vowels. The final stage (from 7 months on) comprises two parallel substages. In the *reduplicated/canonical babbling* substage, starting from 7 months of age, infants repeat speech syllables (e.g., da-da-da). In the *variegated babbling* substage, infants produce combinations of syllables (e.g., ka-da-bu-da). This second substage increasingly dominates the first substage over time.

It is interesting that the first words, which tend to occur at this stage, contain the syllables ma, pa, and na, such as in *papa* and *mama*. Jakobson (1962) has argued that these speech sounds, which contain bilabials and the open vowel /a/, are the simplest to produce. Whether they are really intended to refer to parents, as parents commonly think, is debatable.

Even after the first words have been produced, it takes a long time for infants to learn to pronounce words correctly. Lust (2006) has identified four types of phonological processes that produce errors in early child language: omission of sounds (e.g., 'broke' is pronounced as 'bok'); substitution of sounds (e.g., 'rabbit' is pronounced as 'wabbit'); assimilation of sounds (e.g., 'doggy' is pronounced as 'goggy'); and repetition of sounds (e.g., 'daddy' is pronounced as 'dada'). Several explanations have been proposed to account for these errors. First, infants mispronounce some words because they misperceive them (Lust, 2006). Second, infants need time to learn and optimize the way they use their speech organs to articulate words correctly. Third, the production of correct speech sounds depends on a maturational program, which is universal (Jakobson, 1941/1968). Finally, pronunciation depends on learning and correctly using word patterns or word 'templates.' When these templates are used incorrectly, errors occur (Macken, 1995).

Learning the Meaning of Words

Children's vocabulary learning begins slowly, but rapidly increases – at the age of 16 months children know around 40 words (Bates et al., 1994), yet by school age children learn up to 3000 words each year (or just above 8 words every day) and a 17-year-old learns up to 10 000 words each year (or more than 27 words every day), mainly through reading (Nagy and Herman, 1987).

A classic phenomenon reported in most textbooks on child language is the 'vocabulary spurt': after having learnt around 50 words, children suddenly and dramatically increase the rate at which they learn new words. However, it seems that this spurt is a statistical artifact. When the appropriate statistical analysis is carried out, it appears that, with most children, there is no sudden increase in learning rate (Ganger and Brent, 2004).

At face value linking words to their meaning involves overcoming a number of insurmountable difficulties, of which two have been classically considered as particularly critical. The first is the *reference problem*, discussed at length by the philosopher Quine (1960). When hearing a word (e.g., 'gavagai') in a given situation (e.g., a rabbit scurries by), how does a child (or a linguist) know what the referent of gavagai is? Is it the rabbit, its color, the action of running, some part of the rabbit (e.g., its ear), the time of the day, the color of the grass the rabbit is running on, or an indefinite number of other possible referents? The second problem is the *extension problem*, which is actually common to the acquisition of all concepts, not only those labeled by words. Let us assume that a child learns that 'dog' refers to the family dog ('Snowy'). How does she correctly extend the class of animals and/or objects to which the label

'dog' can be correctly applied? How does she learn that 'dog' not only applies to 'Snowy,' but also to 'Fido' or 'Rintintin?' That it also applies to labradors, greyhounds, and bulldogs, but not to cats and coyotes? That it applies not only to living dogs but also to dogs made of plastic, wood, or metal? And that it does not apply to the parts of a dog, such as its ears or legs?

While these philosophical questions are interesting, they do not seem to bother infants and children – as we have just seen, they learn new words and their meaning fairly rapidly. Thus, an important scientific task is to uncover the mechanisms by which children can avoid the twin problems of reference and extension. A number of theories have been proposed to answer this question, and we briefly review six of them.

Theories Based on Innate Constraints

A first class of theories (Markman, 1990; Landau et al., 1988; Golinkoff et al., 1994) argue that the presence of innate constraints helps infants make the correct inferences when a new word is met. The details differ between the specific theories, and a large number of innate constraints have been proposed, but the following constraints provide a good sample of the kind of innate biases that have been proposed. A first constraint is the *whole object assumption*: when hearing a word, the child assumes that it refers to an entire object (or organism) rather than to its parts. A second constraint, the *mutual exclusivity assumption*, states that objects should have only one name. Thus, for example, if the child knows that the family cat's name is Pepsi, she would assume that words spoken in relation to this cat refer to something other than its name (e.g., they refer to an action or to a part of the cat). A third example is the *noun bias*: infants find nouns easier to learn than other kinds of words. A fourth constraint is the *shape bias*: children tend to label objects that have a similar shape with the same word. As a final example, consider the *principle of extendibility*: children take it for granted that words do not refer to a single exemplar, but rather to a category containing exemplars that share similarity.

Assuming such innate constraints meets with a number of theoretical and empirical difficulties (Rowland, 2014; Ambridge and Lieven, 2011). Theoretically, some constraints would actually make it difficult to learn many words. For instance, in our family cat example, the mutual exclusivity assumption makes it impossible for a child who knows that her cat's name is Pepsi to learn that it is a 'cat.' Another problem is that some of the biases are not empirically valid. Consider the *noun bias* assumption, which implies that nouns are learnt more quickly than verbs. One argument for this (putative) bias is that nouns tend to refer to individuals and concrete objects, while verbs are less directly related to perceptual input (e.g., Gentner, 1982). As it is plausible on biological grounds that more concrete stimuli are learnt more quickly than more abstract ones, if follows that nouns should be learnt more quickly. However, Ambridge and Lieven (2011) convincingly argue that, while this is true for some noun–verb pairs (e.g., *ball* vs *think*), it is not true for others. For example, in the pair *situation* vs *eat*, the noun is less concrete and thus harder to learn. They further argue that the empirical evidence for this phenomenon is weak, as most checklists used by parents contain more nouns than verbs. This bias reflects the statistics of the child's environment: at least in English, the number of nouns is about five times larger than the number of verbs. Nevertheless, the differential number of nouns and verbs creates a methodological problem. Ambridge and Lieven also note that experiments that have found that nouns are learnt more easily than verbs (e.g., Childers and Tomasello, 2002) suffer from the problem that these studies typically use nouns as objects, which means that nouns are selected for their concreteness.

Rather than following innate and universal constraints, it seems that children are sensitive to the semantic characteristics of the language they are learning. This is nicely illustrated in a study by Choi et al. (1999). While English distinguishes between containment (*put in*) and support (*put on*), Korean distinguishes between tight-fit relations (*kkita*) and loose-fit relations (*nehta*). In a preferential looking study with children aged between 18 and 23 months, Choi et al. found that children's eye movement behavior was consistent with the spatial categories of their own language. Thus, the children followed constraints specific to their own language rather than following innate and universal constraints.

Social Pragmatic Theories

As with the previous approach, social pragmatic theories include a variety of specific accounts (e.g., Bruner, 1978; Nelson, 1985; Tomasello, 2003). However, they agree on the key assumption: innate constraints are not necessary for acquiring new words as children can use a number of social cues (e.g., gaze, gestures, movements of the entire body, and facial expressions) to guide their inferences. The concepts of *joint attention* and *understanding of communicative intention* are central in this approach. While these theories are consistent with a fair amount of empirical data, they also suffer from a few weaknesses. For example, as noted by Rowland (2014), children can learn words before they have developed the abilities of joint attention and intention reading. In addition, autistic children learn words to a level similar to that of normally developing children, although they lack precisely these abilities.

Attentional and Associative Learning

A third account argues that word learning simply requires the use of general cognitive mechanisms dealing with attention, memory, and learning (Samuelson and Smith, 1998). Two learning mechanisms are particularly important: associative learning, where an association between two objects is made, and cross-situational learning, where regularities are learnt across situations. While this approach can account for several phenomena, it does not tell the whole story, and it is likely that an account based both on social pragmatics and attentional/associative learning is necessary (Ambridge and Lieven, 2011).

Syntactic Bootstrapping

This approach argues that the meaning of some words, especially verbs, cannot be acquired through a general mechanism

because of their complexity. Therefore, children must use constraints provided by language itself, and they do so by exploiting the information provided by syntax (Landau and Gleitman, 1985). Critics of the approach point out that syntax develops much more slowly than proposed, and thus might be of little use in learning new words (Tomasello, 2003), and that in some languages syntax actually hinders the acquisition of word meaning. For example, Margetts (2008) shows that in Saliba, an Oceanic language spoken in Papua New Guinea, two different verbs express the same meaning (e.g., to give) but are embedded in completely different syntactic structures.

Emergentist Coalition Model

The approaches we have just described focus on one kind of mechanism at a time. A natural extension is to propose an account combining all the mechanisms we have discussed so far. This is what Hirsh-Pasek et al. (2000) did in their emergentist coalition model. The key assumptions are that (1) children are sensitive to a number of cues, including those we have reviewed above; (2) the weight of these cues changes with age; and (3) constraints emerge as language develops. As the model incorporates a large number of mechanisms, it can account for a large amount of empirical data. However, champions of the approaches we have reviewed above retort that the model lacks parsimony, as word learning can be explained by one single mechanism rather than by a large number of them.

Latent Semantic Analysis

Compared to the previous approaches, computational approaches offer a different kind of explanation of word learning. Perhaps the best example is offered by latent semantic analysis (LSA) (Landauer and Dumais, 1997), so we focus on this approach. LSA is a mathematical technique suggesting that word meanings are acquired by exploiting mutual constraints from the language input. With children, these constraints come from interacting with the environment and hearing speech. LSA uses the shortcut of using the paragraphs of a text as a proxy for the episodes we experience in our lives. The central rationale is that the contexts in which a given word does or does not appear powerfully constrain and determine word meanings. Essentially, what LSA is doing is computing correlations between words within different contexts. However, the similarity values estimated by LSA are not simply based upon co-occurrence frequencies, but depend on a deeper statistical analysis (they are 'latent').

Concretely, in its computer implementation, LSA uses as input a corpus of text, where paragraphs define the relevant contextual units. The analysis of word occurrences is carried out across all paragraphs, which makes it possible to compute vectors that represent the meaning and relationships between words. Vectors are mathematically well suited to drawing semantic comparisons between words. To reduce dimensionality, LSA uses singular value decomposition, which is a generalization of factor analysis. Thus, large matrices of word-by-context data (e.g., encyclopedias) can be reduced into 100–500 dimensions. Higher-order co-occurrences are implicitly taken into account by the mechanisms used by LSA. Important contributions of this approach include the description of the acquisition of vocabulary as the construction of a semantic space and the insight that a considerable amount of 'learning' results from indirect induction. However, LSA suffers from two main weaknesses: it does not use syntax or morphology and it cannot handle negation.

Role of Working Memory in Learning Words

Children differ in the speed with which they acquire vocabulary and the number of words they know. Baddeley et al. (1998) have proposed that the phonological loop component of working memory (below, phonological working memory) is the main source of these individual differences. According to these authors, phonological working memory constitutes a bottleneck in the learning of new words. This is due to the fact that, compared to children with low phonological working memory capacity, children with high phonological working memory capacity can maintain more sound patterns in memory. This allows them to learn words more rapidly. Baddeley and colleagues largely support their view using empirical data obtained with the *nonword repetition task* (Gathercole et al., 1994), which they consider to be a reliable measure of the capacity of phonological working memory. In this task, the experimenter presents nonwords of varying lengths and asks children to repeat them back as accurately as they can. One advantage of the nonword repetition task, which uses strings that respect the phonotactic constraints of the language under study, is that it makes it possible to gather a large amount of data whilst at the same time making sure that children do not possess any knowledge of the specific strings that are being used as stimuli.

While influential, this theory suffers from a lack of precision, as it is expressed only verbally. Several computational models have been developed, which provide mechanisms that are better specified. We consider two of these models, one based on connectionism, the other based on the mechanism of chunking.

Gupta and Tisdale (2009) used a 'simple recurrent network' model, consisting of an input layer, hidden layer, context layer, and output layer. In this model, activation patterns represent well-formed phonemic sequences as part of syllabic slots. The model receives input one syllable at a time. Simulations of the nonword repetition test showed that the model captures the overall accuracy patterns, length effects, and error types (i.e., substitution, insertion, and deletion).

Chunking, a mechanism by which units are grouped to build increasingly larger units, is considered a central mechanism of human learning and cognition, including language (Gobet et al., 2001). With respect to the acquisition of vocabulary, Jones et al. (2007) have shown that chunking provides a plausible mechanism for how phonemes are grouped together to form new words. The specific model they use, EPAM-VOC, provides a detailed specification of the way long-term memory (where knowledge of vocabulary is stored) and phonological working memory interact. The model learns by receiving as input child-directed speech and text from storybooks written for children. It captures

key features of children's performance in the nonword repetition task: performance is better for shorter nonwords and for word-like nonwords; performance improves with age; and performance is superior for single consonant nonwords compared to clustered consonant nonwords (Jones et al., 2007). Simulations also suggest that long-term knowledge plays a more important role in explaining individual differences in the acquisition of vocabulary than the capacity of working memory (Jones et al., 2008). Finally, Tamburelli et al. (2012) examine the pattern of children's phonological errors within the syllabic domain. They show that the model captures the fact that children are more likely to make errors at the syllable onset than in the coda position. Thus, the model is able to acquire at least some of the phonotactic rules of English.

Together, the simulations with EPAM-VOC show that the input received by children contains a substantial amount of information, which can be used by relatively simple learning mechanisms to extract the kind of statistical information likely to be useful for acquiring language. They also suggest that developmental changes in the way children perform in the nonword repetition task may reflect differences in the amount of knowledge in long-term memory rather than maturational changes in the capacity of working memory.

Vocabulary Acquisition in Later Language Development

Most developmental psycholinguistics has focused on what happens in the first 5 years of life, perhaps because it is during this period that the greatest challenges are met. One consequence is that there has been little research on vocabulary acquisition in late childhood, adolescence, and adulthood. It is however obvious that there are important changes after early childhood, and that becoming a *proficient speaker* involves much more time than becoming a *native speaker* (Berman, 2007). With respect to vocabulary, there is both a quantitative and a qualitative change. Quantitatively, as seen earlier, individuals learn a considerable number of words during late primary and high school years. Many different sources make it possible to acquire so many words either incidentally or through instruction: school activities, reading books, the Internet, cinema, television, radio, and interaction with peers. Qualitatively, the vocabulary becomes more *marked* (Berman, 2007): it uses longer, more formal, and less frequent words, which often have a highly specialized meaning. In addition, increased use is made of derivational morphology: more words are formed with the help of affixes and compounding (e.g., *un-grateful-ness*). Lexical knowledge becomes more sophisticated, with an understanding and use of synonymy and polysemy. Around the beginning of high school, teenagers become more sensitive to linguistic registers and are able to gracefully and appropriately alternate between casual conversation with all its slang and colloquialisms, and more formal and academic language. In parallel with these changes in vocabulary use, other aspects of language also develop considerably: morphosyntax and metacognition (e.g., critical thinking and use of analogies). This evolution continues well into adulthood, at least with educated individuals.

Conclusion

Like the majority of research on language development, the field of vocabulary acquisition is dominated by the debate about whether language-specific innate constraints are necessary or whether it is sufficient to postulate a combination of general cognitive mechanisms and statistical information in the environment. While the latter theories have gained ground in recent decades, theories based on innate constraints are still championed vigorously. However, as witnessed by the many criticisms we have leveled against most of the theories discussed in this article, our understanding of the way children acquire vocabulary is still poor. As argued by Shatz (2007) for language acquisition in general, what is needed for scientific breakthrough in the field is a better understanding of the information processing abilities underpinning vocabulary acquisition as well as an understanding of the multiple interactions involved, including those between cognitive and social development.

Vocational Education

Alison Fuller, Institute of Education, University of London, London, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In a period of historically high youth unemployment the availability and quality of vocational education takes on particular importance. It is seen by policy-makers and researchers as essential for supporting transitions from education to work, but concepts and purposes of vocational education vary. This article draws on international comparisons to explore the extent to which vocational programs are designed to prepare young people for broad vocational areas and citizenship or more narrowly for specific jobs. It identifies the 'societal approach' as a major way of helping to theorize and explain differences in, and similarities between, national vocational education systems.

Introduction

> Any scheme for vocational education which takes its point of departure from the industrial regime that now exists, is likely to assume and to perpetuate its divisions and weaknesses, and thus to become an instrument in accomplishing the feudal dogma of social predestination.
>
> Dewey, 2010: 214–215

While written nearly a century ago, Dewey's concern about the concept of vocational education and its relationship to work remains highly relevant. In the context of contemporary social and economic imperatives, policy-makers and researchers are questioning the extent to which vocational education pathways should prepare young people for specific jobs; more broadly for a changing, dynamic, and global labor market; and/or for active citizenship in twenty-first century democracies (e.g., OECD, 2010; Pring, 2007). Dewey's observation cogently highlights the persistent tensions that run through national and international debates on the purpose(s) of vocational education, who it is for, what it is, and what it is supposed to achieve and for whom. The importance of vocational education takes on added importance in light of historically high levels of youth unemployment in Europe, the US, and other parts of the world, and the known 'scarring effect' (e.g., Morrell et al., 1994) this has on young people.

Improving education and training is clearly only part of the answer to problems that in scale and scope go far beyond this area of public policy. Nonetheless, national and supranational policy-makers are attempting to create and sustain vocational education systems that can support and facilitate youth transitions from education to work and adulthood in a period of economic hardship and intense global competition for the available jobs. One indicator of this has been the recent international revival of interest in apprenticeship, the development of national policies to support the evolution and expansion of programs, and the means of evaluating their quality (e.g., in terms of their 'expansive' and 'restrictive' features) (Fuller and Unwin, 2012).

The purpose of vocational education can then be viewed on a spectrum with training for specific, narrowly defined jobs at one end and, at the other, a more general preparation designed to help young people leads productive and fulfilling adult lives as workers and citizens. The content of vocational provision will vary according to the underpinning aim. A range of key indicators, including the relationship between general and vocational education, assessment and certification, can be identified that offer evidence about the goal and nature of programs. For example, are participants required to pursue academic subjects such as native and foreign languages, science, mathematics, and humanities alongside their vocational studies; or is their education and training focused primarily on the specifics of the vocational area with minimal curriculum extension and enrichment? There are major differences in the concept and scope of general education within the vocational route. In the UK, it is narrowly defined as primarily English and Mathematics, and has previously been referred to as 'core' or 'key' skills model. Andy Green (1998) has provided a comprehensive critique of this approach, its assumptions, and implications. By contrast in other parts of Europe (e.g., Germany, Austria, and Switzerland), it includes a wider range of academic subjects and civic education (Clarke and Winch, 2007).

There are also related questions about the settings in which learning in the vocational route takes place: Are participants primarily located in the workplace with little off-the-job or classroom provision; is it the other way round with full-time attendance in vocational school or college and little opportunity for workplace experience, or is it a structured combination of participation in both workplace and classroom? Moreover, to what extent is the program designed in terms of the teaching and learning of vocational knowledge, including the relevant underpinning scientific, technical, and social theories, or around a list of occupational competences and standards that participants need to show they have met.

Issues of assessment and certification are relevant here too. The purpose and nature of the program will be reflected in how participants are assessed. This may include whether they sit formal written examinations and are examined separately on the general educational element of their program. If so, does this enable them to achieve dual certification for their academic and vocational achievements which facilitates movement between different kinds of programs, or is assessment confined to accrediting the acquisition of vocational competence and occupational expertise, for example, through observations in the workplace? Beyond this, what is the currency of the qualifications participants achieve for progression to higher

 http://dx.doi.org/10.1016/B978-0-08-097086-8.92091-9

education (HE) and entry to Bachelor degrees, or for entry to the skilled labor market? In concerning itself with questions such as these, this article provides an overview of some of the key debates and theories permeating discussions about vocational education, what it consists of and how it is positioned in wider educational and employment landscapes.

Vocational education and training (VET) can, of course, also be used as a route back into employment (e.g., for unemployed adults or women returning to the labor market after raising children), or to more highly skilled work and jobs for those already in employment, but the focus of this article is on initial vocational education for young people.

Why Is Vocational Education Important?

There are various reasons why vocational education matters. At one level the answer is all around us. Building the infrastructure that supports modern life, curing the sick, maintaining and repairing machinery and equipment, providing hospitality and leisure services, technological innovations in telecommunications and more, are only enabled by the availability of people with occupational knowledge, skills, and expertise. The need for vocational education for instrumental reasons, then, is obvious. However, going beyond this and getting to the heart of John Dewey's concern is a call for a holistic and humanistic concept of vocational education that recognizes the inherent and intrinsic values associated with learning for occupational expertise and practice of skilled work, for the individual and wider society (Sennett, 2008). Lorna Unwin has suggested that this broader understanding of vocational education should be reflected in all education (2009).

Most debates about the importance of vocational education and, in particular, the need for its reform, do not start with such philosophical concerns. For the most part, commentators invoke two main and often conflicting discourses. Firstly, in policy terms vocational education has increasingly been associated with economic competitiveness (OECD, 2010; EU, 2002). In the Lisbon Agreement, the European Union (EU) explicitly stated its goal (by 2010) to become "the most competitive and dynamic knowledge-based economy in the world" (Council, 2000: 3) later identifying the "crucial contribution from education and training as factors of economic growth, innovation, sustainable employability and social cohesion" (Council, 2002: 5 both cited in Ertl, 2006). The argument underpinning this and other 'competitiveness' policies is based on the assumption that improving the quality of VET has a positive effect on competitive advantage through generating greater productivity and facilitating innovation. Studies by Sig Prais and colleagues in the 1980s compared the productivity of matched plants in Germany and the UK, concluding that the better performance of German firms could be explained at least in part by the superior vocational preparation of their workers (e.g., Prais et al., 1989). Subsequently, this idea has been developed to suggest that the availability of a skilled workforce allows more productive forms of work organization where employees have more discretion and involvement in the decision making, and the development of higher value-added products and services (Finlay et al., 1998, see also Keep et al., 2006 for a critique of these assumptions). It follows that countries with highly developed and effective VET systems are likely to be more successful in the global economic competition, Germany is probably the country most often given as an example here.

Secondly, vocational education is viewed as a pathway to stable employment for school-leavers who do not progress to HE. In other words, it can be conceived as a 'transition system' for part of the cohort (Raffe, 2008). In some countries the vocational route is also seen as a vehicle for reengaging disaffected young people and social inclusion (Preston and Green, 2008; EU, 2010).

The existence of academic and vocational educational pathways raises the issue of comparative status between the two routes. The dualistic nature of much of the discourse around vocational education (Clarke and Winch, 2007; Pring, 2007; Young, 2004) represented by the academic–vocational, theory–practice, mental–manual, education-training binaries is unhelpful. A point also picked up by the American philosopher Richard Sennett in his recent book *The Craftsman*:

> History has drawn fault lines dividing practice and theory; technique and expression; craftsman and artist; maker and user; modern society suffers from this historical inheritance. But the past life of craft and craftsmen also suggests ways of using tools, organizing bodily movements, thinking about materials that remain alternative, viable proposals about how to conduct life with skills.
>
> Sennett, 2008: 11

Linda Clarke and Christopher Winch highlight how language provides a window on the contrasting values and meanings attributed to vocational education. For example, the German language has three terms that signify three different conceptions of the English word 'training' "first, in the sense of to train an animal … [where German] uses the verb *abrichten* …, second, to train someone to carry out a specific job or activity … *anlernen*; and, finally, the sense of education for an occupation like medicine or carpentry, where German uses *ausbilden*" (2007: 7). The language point is significant because it highlights cultural distinctions in the way VET is conceptualized and understood, and suggests that transferring the characteristics of vocational education from one country to another is far from straightforward. Different ways of conceptualizing and characterizing approaches to vocational education and their consequences for convergence and divergence between systems will be discussed in the next section.

Why Do Different Models of Vocational Education Exist in Different Countries?

There are various ways of organizing and providing vocational education. This can be seen in the diverse models of vocational education that exist in different countries. Given the national and international policy interest in the link between VET and economic competitiveness, researchers have examined the characteristics of systems and ways of grouping countries with similar institutional arrangements. In the main, international comparative research over the past 25 or so years has drawn on original empirical and theoretical work undertaken by French

scholars Maurice et al. (1986) who developed the 'societal approach.'

> The societal approach emphasises the holistic interrelationships among different social and economic institutions, including education and training, the labour market and industrial relations systems, the production system, family structures and cultures, and so on.
> Raffe, 2008: 278

Maurice et al. (1986) analyzed the relationship between education, the labor market, and other civic and social institutions in Germany and France. They identified that the nature of this societal relationship was distinctive in each country. Given strong evidence from the cross-national research literature, including some of the most extensive studies of country differences in the logics that underpin their vocational education systems (e.g., Hannan et al., 1997; OECD, 2010), it is not surprising that the extent to which countries converge or diverge has been a key area of debate (Müller and Shavit, 1998; Raffe, 2008).

A number of country typologies deriving in the main from the comparison of national data sets and cross-national surveys have been developed, drawing on dimensions and concepts that help classify countries into types. A review of the comparative literature suggests that three of these are particularly important and tend to be interrelated, 'logics and linkages,' 'standardization,' and 'stratification.' Firstly, as Ianelli and Raffe (2007) suggest the strength of the links between vocational education and the labor market varies from country to country depending on their industrial histories, civic and democratic culture, and the associated institutions and arrangements that have grown up in the relevant country context. They suggest that countries where the linkages between vocational education and employment are weak (e.g., Sweden) operate in line with an education logic, whereas those where linkages are strong can be viewed as having an employment logic. The nature of the labor market and particularly how it is regulated is a relevant factor here. The employment logic is strong in countries (e.g., Denmark and Germany) where entry to skilled occupations is regulated and restricted to those who have completed an agreed (according to existing institutional arrangements) vocational program (usually in the form of an apprenticeship) and achieved the required qualifications. It is less strong in countries such as the UK and the US which traditionally have been viewed as having more flexible and open labor markets, with access to occupations being less heavily regulated.

Secondly, the concept of standardization refers to the content of vocational curricula and the processes by which they are followed and assessed. The extent to which a vocational pathway is standardized in terms of the curriculum, assessment regime, and qualification(s) has an impact on how well employers understand and recognize the learning and achievements of those who have successfully completed it. Standardization makes it easier for employers to recognize the currency, and to trust the use value of the qualifications (extent to which they can be taken as a reliable proxy for the knowledge and competence award holders) achieved by participants. Allmendinger (1989) identified the importance of standardization, suggesting that young people experience much more straightforward transitions into work in systems with uniform standards. Given the role of standardization in supporting education – work transitions, it follows that countries whose approach to vocational education is characterized by employment logic are also likely to have standardized provision.

Thirdly, stratification refers to the proportion of young people staying in school for as long as the system allows (Allmendinger, 1989). Put another way, if a country's compulsory education system requires students to remain in school until the age of 16 but a further 2 or 3 years of upper secondary schooling are available, then what proportion of the cohort are able or choose to stay on? The more highly stratified the system, the smaller the participation rate in the final post-compulsory years of school and the higher the participation rate in other pathways, for example, apprenticeship. A further consequence of a highly stratified system is the smaller proportion of young people progressing to university. Hence countries with mass participation in HE such as Korea, Japan, and Canada tend to have smaller and weaker apprenticeship systems than countries with lower rates of participation in university such as Germany. The OECD *Education at a Glance* (2012) figures show that approximately 65% of Koreans aged 25–34 years have attained a higher level qualification compared with 25% of Germans in the same age group.

The identification of country typologies suggests that there is a relationship between logics and linkages, standardization and stratification. For example, Kerckhoff (2000) has proposed two 'types.' Type 1 societies (e.g., Germany) can be distinguished by their strong standardization, stratification, and linkages between vocational education and the labor market. In contrast, Type 2 societies (e.g., USA) have been characterized by nonstandardized programs, less stratification, and looser linkages between vocational education and employment. Some countries such as the UK and France are harder to classify and so have been viewed as falling between the two types. This suggests that the dimensions could be usefully perceived as continua, rather than either/or categories. Other typologies have focused primarily on patterns of participation. For example, Andy Green et al. (1999) identify national apprenticeship systems as high, low, or medium participation.

A key factor in the distinctiveness of a country's approach to and organization of vocational education is the role the state plays in the configuration of institutional and societal relationships that underpin its vocational education system. Understanding the role of the state in creating and supporting education – work pathways and transitions shed light on the strength of its interest and involvement in this area of policy (Green, 1990). Drawing on ideas from political economy, David Ashton (2004: 21) argues that in addition to the societal approach (outlined above) VET policy "is also conditioned by the state structures and the ability of the state to administer a central policy initiative." From this starting point he develops a typology of national systems that includes three models. Firstly, the 'free market' model (including the US, the UK, and Canada) is based on a long tradition of the state's 'laissez-faire,' voluntaristic approach to intervention in the relationship between capital and labor. In this model, the role of the state is to provide a legal framework that supports the workings of

market forces and underpins the 'dominance of capital over labor' (Ashton, 2004: 23). It follows that the main contribution of the state, here, has been to create and maintain an education system that provides citizens with basic general education and orientation to work. Thereafter the responsibility for building on this foundation lies with individuals and employers. VET provision can be bought from providers or supplied directly by companies, for example, in the form of on-the-job training.

Secondly and by contrast, in the 'corporatist' model (including Denmark and Germany), the state intervenes in the capital – labor relationship, thereby, producing a social partnership approach (also involving the Trades Unions) to achieving initial industrialization and later economic development. This model is underpinned by shared support for and involvement in the education and training system.

> The achievement of a consensus with the social partners means that this model creates a more institutionally dense environment for training, usually focused on the apprenticeship system.
>
> Ashton, 2004: 24

Thirdly, the 'developmental state' model (including South East Asian economies such as South Korea and Singapore) reflects an approach where, starting from a low industrial and educational base, the state has taken the leading role (since World War II) in promoting industrialization, and in shaping industrial relations and the education and training system.

In drawing attention to the different roles played by the state in the three models, Ashton is able to make further important points about the relationship between national VET systems, work, and employment. Leaving vocational education primarily to employers (free market model) means that provision is more likely to be narrow and task specific to meet the needs of particular organizations (i.e., nonstandardized). Where, as in the corporatist model, the consensus approach produces highly skilled workers (via standardized occupational apprenticeships), the challenge is how to adapt the system to meet new needs flowing from rapid technological innovation. In the case of the developmental state model, where the state plays a highly active not-to-say dominant role, it can push employers 'to adopt new methods of production' and individuals 'to learn the appropriate skills' (p. 34). In the context of an increasingly competitive global economy, then, it is apparently not enough for countries to create and sustain vocational education systems. In addition, the character of jobs created, linked to the mode of production and competitiveness strategies adopted by countries, sectors, and companies can act as a pull factor shaping what is required from the vocational education supply pipeline.

The discussion so far has suggested that there is a relationship between the purpose and nature of the vocational education pathway and employment and occupational opportunities. In other words, insights about the nature of the labor market, the kinds of jobs available, their status and grade, the way skills are constructed and rewarded, can be gained from studying the vocational education system and vice versa. Put more strongly, I would suggest that there may actually be a wash-back effect on the status, purpose, and nature of vocational education from the distribution of good quality (secure, well-paid, full-time permanent, respected status) jobs in national and sectoral labor markets. This raises the question of what kinds of jobs nation-states are preparing their young people for. Lorna Unwin has observed that in the UK politicians and policy-makers make denigrating assumptions about low-grade jobs being performed by individuals who are deficient in knowledge and skills. She criticizes this analysis and the policy 'solution' (which it can be noted is consistent with Ashton's free market model as the state stops short of proactively intervening with employers):

> … at the same time as being dismissive of many occupations, policymakers have become fixated on the individual as the source of the problem, and, hence, millions of pounds are being poured into the acquisition of qualifications without any parallel initiatives to improve job quality.
>
> Unwin, 2009: 2

It follows that enterprises that organize work and production in ways that foster the creation of jobs designed to foster employee discretion, involvement, and contribution are more likely (1) to feed into and support the development of a high-quality initial vocational education system from which to select well-educated and able staff, and (2) to create workplace learning environments capable of fully utilizing and further developing their skills (Fuller and Unwin, 2004; Felstead et al., 2009).

Characteristics of Vocational Education Pathways and Some Implications

In broad-brush terms, vocational pathways can be viewed as school-based, where students follow full-time programs of study linked to a broad vocational area such as business, economics, and commerce in a formal educational institution; apprenticeship, where apprentices are placed (and usually employed) in a company where they receive on-the-job training (usually) coupled with regular off-the-job training (such as day release in college); or mixed, where the vocational system includes both apprenticeship and school-based modes of participation. David Raffe (2008: 285) suggests that pathways can be analyzed along four dimensions:

- Size of vocational pathway in comparison with general education – the proportion of the cohort pursuing each route
- Nature of vocational pathway – particularly extent to which it is school-based, work-based, or a mixture of the two
- Occupational specificity – the degree to which the program is narrowly job specific or more broadly focused on a vocational area
- Relationship between general and vocational pathways – the degree of commonality between the modes of participation, pedagogy, assessment, and certification associated with each, and the ease of movement between them.

These four are key dimensions for illuminating the general character of the pathway but it is also worth identifying some other issues. In addition to the size of the vocational pathway, the main setting in which it is followed, the degree of

occupational specificity and the extent to which there is standardization and permeability between general and vocational pathways, it is important for social justice reasons to ask who is participating in what pathways: How evenly are young people with different social class, race, and gender characteristics represented across the system? Linda Clarke (2007: 63) discusses the role of vocational education in reproducing rather than challenging social inequalities. She argues that the institutional arrangements (discussed earlier in terms of the societal approach) that underpin the shape and structure of VET also reflect historically entrenched 'class and gender relations.' Stereotypical patterns of participation by females and males in vocational courses and apprenticeships continue to persist (Lakes and Carter, 2004) with young women being strongly overrepresented in fields such as hairdressing and child care and underrepresented in engineering and construction, sectors that are dominated by young men. Historically, the ability of institutional gatekeepers (e.g., the guilds, professional bodies) to oversee or even restrict entry (numbers and characteristics) into apprenticeships and occupations can have the effect of maintaining wage levels and job status:

> It [vocational education] is about entry into the labour market; about dividing up the potential labour force into different occupations and skills, each with a distinct quality. And it is about class and gender divisions, acting as a filter to include or exclude particular groups from particular occupations or industries and from acquiring a particular status in society.
>
> Clarke, 2007: 62

The classed nature of who participates in what pathway has been illuminated in highly insightful research by Shavit and Müller (2000). They drew attention to the 'diversion effects' of vocational education systems where most young people do not participate in HE and where, in a strongly stratified system (such as in Germany), it is hard to move between tracks. Their findings indicated that those from lower socioeconomic groups were more likely to be found in the apprenticeship pathway than their more socially advantaged peers. On the other hand, the more regulated nature of the labor market and the involvement of the social partners in designing and supporting apprenticeship meant that it usually provided a strong 'safety net' for participants (male and female) and vehicle for supporting their transitions to skilled jobs and permanent employment. There are few signs that the renewed international interest in expanding the apprenticeship route is, as yet, challenging gendered patterns of participation, although during the 2000s there have been some useful vocational education initiatives sponsored by the EU that have produced some positive outcomes (Fuller and Unwin, in press).

In addition to examining the characteristics of the population participating in vocational pathways, it is important to focus on content and in particular the approach taken to vocational knowledge (Winch, 2010; Bathmaker, 2013). In the UK this has been a strongly contested issue, as researchers and academics have critiqued the marginalization of knowledge in the outcomes-based design of National Vocational Qualifications (NVQs), which have dominated the VET system since the early 1980s (for a critique of NVQs see Grugulis, 2003).

Michael Young (2004) has identified and discussed distinctions between three approaches to knowledge and the vocational curriculum which he has related to different periods in the development of vocational education in the UK since the late nineteenth century. These also serve as useful lenses for analyzing the approach to knowledge in vocational education more widely, including in other countries. Firstly, the 'knowledge-based' approach arose from the perceived need for apprentices in engineering and science-based industries to be taught relevant scientific subject knowledge. It "assumed that the natural sciences were important for their specific content and as a model of reliable, objective knowledge" (Young, 2004: 187). This model was later extended to other vocational areas such as business studies which were taught in further education colleges (the main institutions providing vocational education in the UK).

Secondly, the 'standards-based' approach introduced in the 1980s arose from policy-makers' criticism of the knowledge-based model which they felt had become too academic and removed from what employers required. The new approach used functional analysis to develop occupational standards in line with employers' requirements. Individuals were deemed to be competent (through an accreditation process in the workplace) if they could perform tasks to the specified standards. The principal weakness Young (2004: 191) identified with the first model is that it "failed to consider how this new [scientific subject] knowledge could be recontextualised in the workplace." He went on to argue that the second model "neglected the extent to which only some of the knowledge relevant to particular occupations has its origins in workplaces," and therefore provides an emasculated approach to vocational knowledge. In response, Young identified a third model 'the connective approach' which aimed to overcome these limitations by combining theory and practice, and on and off the job learning. Michael Young and others (e.g., David Guile, 2010; Young, 2008; Winch, 2010) have gone on to develop ideas about the nature of vocational knowledge and expertise and how it needs to be reconceived, positioned, taught, and learned in the context of contemporary vocational and professional education and the dynamics of changing patterns or work organization and production.

Recent studies of the content and inclusion of vocational knowledge in full-time vocational courses and apprenticeship frameworks in England (Brockmann et al., 2010; Fuller and Unwin, 2011a,b; Bathmaker, 2013) have found continuing shortcomings inviting negative comparisons with the quality of vocational education in other countries.

It is also important to consider the value and worth of qualifications attained by participants in vocational education pathways. To what extent do they provide a strong platform for career and educational progression, and to what extent do they articulate and so support horizontal bridging to general educational pathways and vertical ladders to HE? To explore this, I draw on a recent EU Leonardo funded project on 'hybrid qualifications' (HQ) in England, Denmark, Germany, and Austria (Deissinger et al., in press). The

study explores the ability of qualifications positioned as providing both general educational and vocational currency to lead either to employment in the skilled labor market or to a place in HE. The focus of the research reflects the EU policy aims of improving the permeability and progression opportunities within and between national vocational education systems.

In England, Germany, and Denmark there was no well understood or established hybrid pathway that catered for a clear population of young people of upper secondary age. In Germany and Denmark the stratification of the school system into different academic (gymnasium) and vocational institutions (vocational schools and dual system apprenticeship) and tracks led to limited opportunities for movement between them. Moreover, the qualifications attained by young people in each track are not portable such that those who achieve the academic diploma are not qualified to enter the skilled employment in the regulated occupational part of the labor market, and those who successfully complete their apprenticeships do not accrue the qualification currency to access HE. There are experiments underway in both countries to try and develop HQ routes but, in the main, opportunities for vertical progression (either to the labor market or HE) rely on individuals gaining qualifications from both pathways (double qualifications) (Deissinger and Wern, 2011; Jørgensen and Lindvig, 2011).

In England the system is less stratified and standardized but the linkages to the labor market are looser (Davey and Fuller, 2011). Young people populating the middle or hybrid space can progress to HE if they attain a combination of academic and vocational qualifications through full-time study but there is no automatic labor market recognition of these attainments. Alternatively, those following the apprenticeship route are in employment, although the variable quality of programs (and limited labor market and occupational regulation) means that the strength of apprenticeship as a platform for career progression is uneven. The difficulty for apprentices is progression to HE because the currency of the qualifications available in their frameworks is usually insufficient for entry to Bachelor degrees, even those in subject areas that are cognate with the apprenticeship.

In Austria, by contrast with the other three countries, there is a well-understood and established hybrid route within a system that is characterized by stratification and standardization. The hybrid option sits between the country's solely academic pathway followed by approximately 20% of the cohort through the attendance at the gymnasium and its dual system (vocational school and work-based) apprenticeship route followed by approximately 40% of the cohort. Young people (approximately a third of the cohort) participate in the hybrid route where they attend specialist educational institutions known as vocational colleges. The distinctive feature of the vocational college provision is that it leads to a certificate of secondary education (the same Reifeprufung examination as their gymnasium peers) and a VET diploma supplemented with additional specific labor market qualifications. College graduates with these achievements possess the recognized entry qualifications to access the full range of university courses in as well as skilled employment (Aff et al., 2011).

Conclusions

The article began by contrasting a far-reaching, holistic conception of vocational education with a narrow occupationally specific alternative, indicating the range of purposes it may be required to fulfill and the unhelpful persistence of the academic–vocational divide. The ensuing analysis of national vocational education systems has indicated some of the important dimensions along which they can be differentiated and some of the implications for social justice and inclusion, as well as for educational and career progression.

The brief discussion of the HQ study illustrated the uneven value and portability of qualifications, and the scale of the challenge involved in fulfilling the increasingly popular (national governments, EU, OECD) aim of increasing permeability between pathways and progression opportunities from vocational education to HE and skilled employment. Case study comparative research is important here as it provides an effective way of identifying and explaining the diverse characteristics of vocational education systems. Evidence can be generated that shows, on the one hand, how approaches to vocational education reflect deep-seated historical, cultural, economic, and institutional differences between societies and, on the other, how external pressures and economic forces (e.g., related to the negative economic effects of the banking crisis, changing industrial structure and patterns of international labor mobility, and technological innovation) provide a transformed context with which all industrialized countries are grappling. Young people are particularly vulnerable to unemployment and to experiencing barriers to their successful transition to fulfilled adult lives and citizenship. The extant literature suggests that the availability of good quality vocational education can facilitate transitions, but contextual factors mean that what counts as effective, for whom, and in whose interests, is likely to continue to differ.

Abstract

This article presents a brief summary of the classical psychological theories of vocational interest (e.g., the Holland model). Next, it explores how insights from other subfields of psychology (e.g., developmental, positive, and social psychologies) have contributed to new understandings of how vocational interests form. Drawing on recent literature from these different domains, this article provides a synthesis of the current state of research into vocational psychology.

Introduction

Given that most adults spend nearly half of their waking hours at work, the psychology of vocational interests and preferences provides critical insights into the relationships between occupation and personal fulfillment (Robinson and Bostrom, 1994; Robinson and Godbey, 1997). Recent evidence suggests that workers whose occupations are strongly matched with their interests perform better at job tasks than those with weaker matches (Nye et al., 2012). Research also indicates that occupational competence and satisfaction is by in large an important determinant of overall satisfaction and happiness with life choices (Erdogan et al., 2011). Consequently, the study of vocational psychology is relevant for both predicting occupational choice and understanding the determinants of general well-being.

Traditionally, vocational preference theory has focused on matching one's personality type to an appropriate career as determined by the characteristics of the workplace environment including flexibility for making decisions, challenges, and complexity of tasks typical of that career (e.g., Holland, 1997). More recently, researcher emphasis has been to examine more closely how work-related interests form during childhood through adolescence and how these interests are reflected in later education and career choices (Krapp, 2007; Chope, 2011). This change is largely the result of findings that link vocational interests and educational expectations and attainment (Patrick et al., 2011). Empirical results further suggest that those whose occupational aspirations and educational expectations are misaligned have greater difficulty constructing a reasonable life path that leads to job stability and higher wages (Sabates et al., 2011).

This article begins by discussing theories of vocational preference and related empirical research initiatives. Next, several models from educational psychology are introduced that can be applied to understanding individuals' vocational interests. We conclude by describing contributions from positive psychology that have increasingly changed the scope of vocational psychology from one concerned primarily with work preferences and job satisfaction to one that considers overall life-course satisfaction. We take this direction, in part as it is estimated that jobs are likely to change frequently during young adulthood suggesting that vocational interests may be more porous than some have assumed (Bureau of Labor Statistics, 2012).

Foundations of Vocational Psychology

While theories of the source of vocation interest have existed since the 1900s with Parsons (1909); followed by Strong (1943), the basic foundation of vocational psychology can be traced to the work of John L. Holland (1959). (See Gottfredson (1999) for a synthesis of Holland's contributions.) Fundamentally, Holland's theory of job satisfaction, stability, and performance depends on matching one's personality with job environment. Holland identified six personality types: Realistic, Investigative, Artistic, Social, Enterprising, and Conventional (abbreviated as RIASEC), each of which can be characterized by a combination of interests, preferred activities, beliefs, abilities, and values. These personality types are linked to work environments that correspond to the same dimensions as the RIASEC categories. *Congruence* occurs when the worker personality type and vocational environment are complementary resulting in the likelihood of increased worker satisfaction compared to other situations where personality type and environment are not compatible. It is important to underscore that the idea of 'fit' between personality and environmental conditions has been adapted and modified to explain congruence and lack thereof in examining the relationships between individual dispositions and the characteristics of various social contexts such as family, peer groups, and classrooms and their reoccurring psychological and social qualities (Cook et al., 2002).

There are numerous measures of vocational interest; two of which have been widely used for assessing the validity of Holland's model including the Vocational Preference Inventory (Holland, 1965) and the Self-Directed Search (Holland et al., 1994). In addition to this classical measure of vocational interests, the Strong Interest Inventory, updated in 2004, provides information that corresponded to Holland's model (Donnay et al., 2004). A recent *meta*-analysis that included 60 different studies based upon Holland's model and similar vocational interest inventories found that vocational interest was a strong predictor of a wide variety of measures of education and work performance (Nye et al., 2012).

In the Nye et al. *meta*-analysis spanning over 60 years, correlations between interests and performance were calculated for four performance criteria – *task performance* (efficacy at completing assigned tasks), *organizational citizenship behavior* (OCB; being helpful coworkers), *persistence* (tenure with an employer), and *counterproductive work behavior* (CWB; actions that detracted from the completion of one's own tasks or the tasks of others). The relationship between these measures of performance were analyzed both with respect to interest by itself and then with indices of congruence. Results show that the positive correlations were stronger for the congruence indices of task performance, OCB, and persistence than interest alone, but the negative correlation with CWB was quite weak. Similar patterns were also observed when academic outcomes – grades and persistence – were used as outcome measures. The authors interpreted this analysis as positive evidence for Holland's theory of congruence.

In addition to Holland there have been numerous measures of vocational interest. Borgen (1986) and Rounds (1995) provide a detailed comparative overview of these and earlier measures of vocational interest that are no longer as widely used, such as the *Kuder Occupational Interest Survey* (Kuder and Zytowski, 1991). For a more recent comprehensive historical review and overview of current advances in the measurement of vocational interest, see Armstrong et al. (2011).

An Educational Psychologist's Conception of Interest

Psychologists use the term 'interest' to describe the enjoyment and willful engagement in an activity or task (Schraw and Lehman, 2001). The important role that interest plays to promote learning was recognized by early psychologists, including Johann Friedrich Herbart, William James, and John Dewey (Hidi, 1990; Schiefele, 1991). Two key constructs from this work include *personal* and *situational* interest. Personal interest is the disposition toward a type of activity based on past experiences and is relatively stable over time; situational interest refers to a temporary state that is prompted by a certain set of circumstances or stimuli. Holland (1997) incorporated aspects from both types of interest in his model of vocational interest. The six personality types are essentially manifestations of personal interest and relatively immutable traits whereas vocational interest is contextually dependent. Today, psychologists typically make a distinction between 'personal interest' and 'situational interest' and consider the construct as having both a cognitive and affective component (Hidi and Harackiewicz, 2000).

The distinction between personal interest and situational interest need not necessarily be dichotomous and discrete. A number of developmental psychological models have sought to integrate the two constructs. One such model is the four-phase model of interest development (Hidi and Renninger, 2006). In their model, while each prior phase is requisite to achieving the next phase, there is no guarantee that subsequent phases will be achieved: Phase One – 'triggered situational interest' – is a response to external stimuli that captures the individual's attention, perhaps because it is novel, unexpected, or unusually intense. Phase Two 'maintained situational interest' – occurs sometime after Phase One and is distinguished by an unusual level of strong concentration over a prolonged period of time. Maintained situational interest requires external stimulation to initially capture the individual's attention; however, attention is maintained as the subject of interest is personally meaningful. Phase Three – 'emerging individual interest' – represents a combination of psychological state and a nascent form of predisposition to seek out the subject of interest. The individual is aware, perhaps subconsciously, that similar past experiences have offered rewarding opportunities for personal fulfillment welcoming an opportunity to re-engage. Phase four – 'well-developed individual interest' – is also both a psychological state and stable personality trait. An individual does not require any external stimuli to promote a desire to undertake an activity, object, or task of interest. Someone who has achieved this level of interest will actively seek out opportunities to engage with the subject of interest, so one might consider this a pure form of personal interest.

The extant literature in vocational psychology has consistently shown that interests stabilize as one transitions from adolescence to early adulthood (Low et al., 2005). This finding is intuitively compatible with the four-phase model of interest development for several reasons. First, the likelihood of encountering a truly novel stimulus decreases as one's frame of reference toward the world increases. Second, as one ages, the more likely it is that previously well-developed interests may crowd out other less valued ones. Since individuals are constrained by limited time and capacity to pay attention, choices on what interests to cultivate compete with one another. The next section provides a framework for describing how individuals prioritize education pathways and perceived vocational opportunities.

Expectancy-Value Theory

Another major contribution from educational psychology that examines the origins of vocational choice is the modern expectancy-value theoretical framework developed by Jacquelynne Eccles, Allan Wigfield, and colleagues (e.g., Eccles, 1983; Eccles et al., 1989; Wigfield and Eccles, 2002; Wigfield et al., 2009). The primary application of this theory is to explain educational outcomes such as the selection of college and career choices based on a series of constructs such as achievement, values, and familial social contexts. The theory posits that opportunity costs are constrained by personal choices regarding the time and effort they invest in specific activities and tasks. Individuals choose between activities based upon future expected benefits and the perceived likelihood of success, which are referred to as *expectancy* and *task value*, respectively.

The construct of expectancy is based upon answers to questions such as, "Can I successfully complete this task?" The foundation of expectancy is past experience with similar tasks, and projected future competency. Expectancies are also based on prevailing social norms, expectations of others such as parents, peers, and teachers, and other external signals. For example, a consistent finding in this literature is that females often experience negative feedback with respect to their competence in mathematics, which becomes integrated into

the formation of their expectancy task value. A complete exploration of these stereotypic responses to particular situations is beyond the scope of this article, but social psychology explores the nature and mechanisms through which these perceptions form and propagate (for a comprehensive review, see Gilovich et al., 2006).

Individuals also construct task values based upon the answer to a question such as "Do I value the future returns of doing this task?" Essentially the individual is assumed to be a rational actor who calculates the expected future benefits of undertaking an activity against the expected future costs subject to information constraints. For example, a young child who fantasizes about being a professional baseball player as an adult is much more likely to want to practice hitting in a batting cage than a peer who does not share that aspiration. It should be noted that as individuals transition from childhood to adolescence and into early adulthood, their task values become more realistic as they obtain more information about the world (Schneider and Stevenson, 1999).

Within this theoretical framework, both expectancy and task value represent necessary, but individually insufficient conditions for motivation. For example, an individual who believes that success is attainable in a particular activity but sees no potential future value in undertaking it will be relatively unmotivated to pursue it. Similarly, an individual who lacks the confidence to succeed will be unmotivated regardless of the value of the perceived goal. When an activity satisfies both conditions, there is a positive feedback in the sense that the individual now has a positive experience that will increase future expectancies for similar activities. Early life educational experiences, termed *affective memories*, are integral to the development of vocational interests. Over time, a collection of positively reinforcing expectancies leads to relatively stable affinities toward those activities that eventually manifest as preferences toward certain academic subjects and career decisions.

The construct of task value can be further refined into four components: *attainment value*, *utility value*, *intrinsic interest*, and *cost belief* (Eccles, 1983). Attainment value represents the nexus between tasks and self-identity. Particularly for children and adolescents, the tasks that one undertakes play a critical role in determining how they perceive their own identity and sense of self. For example, to an adolescent, playing a trumpet in a jazz band not only represents a potentially rewarding activity that is intrinsically motivating, but may represent an essential aspect of how the student perceives him or herself, in this instance as an aspiring musician. Utility value represents the tangible benefits that the individual hopes to realize in the future. For example, a high school student who wishes to become an engineer may persevere through a difficult AP Calculus course because mastery of the material is necessary to gain admission to a competitive undergraduate engineering program. Even if the student does not enjoy the mechanics of solving the problems, he or she may still be motivated if they perceive that successful completion of the course will provide opportunities that the student views as particularly salient for realizing future ambitions.

Intrinsic interest is defined as the genuine enjoyment in undertaking a task that naturally develops from previous experiences. Specifically, within this framework, intrinsic interest develops from affective memories retained from similar tasks in the past. Cost belief refers simply to the anticipated effort required to acquire the level of attainment value that the individual seeks. For example, in the previously mentioned jazz trumpet player, one cost belief might include the amount of time of daily practice that the individual believes is necessary to obtain the level of proficiency to which he or she aspires.

Expectancy-value provides a widely used theoretical framework for describing the development of motivational beliefs, particularly in children, adolescents, and young adults. Numerous empirical studies confirm the validity of the framework within the educational context. Specifically, with respect to one's plans to take courses as well as enroll in them, a great deal of empirical research has shown that attainment value, intrinsic interest, and utility value are stronger predictors than discrete vocational preferences (Eccles, 1983; Meece et al., 1990; Wigfield and Eccles, 1992). In addition, confirmatory factor analysis has empirically established the validity of the constructs (e.g., Eccles and Wigfield, 1995). A thorough review of these findings is presented in Wigfield and Eccles (2000).

Flow Theory

Over the past decade, vocational psychology has increasingly integrated the insights and perspectives from what has become known as positive psychology. One of the foundational theories of this subfield is flow theory. Csikszentmihalyi (1985) describes flow as "The holistic sensation that people feel when they act with total involvement" (p. 36). The state of flow is most easily achieved when an activity presents a match of high skill and high challenge (Csikszentmihalyi, 1997). Beyond fostering contemporaneous engagement in an activity, flow is critical to interest formation because flow represents a positive experience and students will likely repeat activities in which they have previously experienced flow (Csikszentmihalyi, 1997). Csikszentmihalyi and Massimini (1985) posit that the psychic rewards of a flow experience (e.g., an increased level of enjoyment, self-esteem, sense of control) will encourage the student to seek to repeat flow experiences by finding similar opportunities; thus flow, like task value expectancy theory, provides positive feedback that encourages the individuals to continue studying academic subjects that initially engaged them.

Flow represents a theoretical framework that informs not simply the 'in-the-moment' engagement, but also provides insight into how the accumulation of experiences contributes to interest formation over time. In other words, the theoretical framework of flow provides a lens into understanding both how educational experience shapes the formation of intrinsic interests as well as what determines task satisfaction in the present. This dual explanatory power of flow occurs because the essence of the flow experience is the individual's enjoyment of intrinsic rewards simply from undertaking the activity itself (Csikszentmihalyi, 1990), which is perceived as more effective at fostering learning than various forms of extrinsic motivation (Deci and Ryan, 1985). Recent research confirms that intrinsic motivation is positively associated with 'deep learning,' while extrinsic motivation is associated with 'surface learning' (Moneta and Spada, 2009). For this reason, flow theory provides a useful lens into student engagement within an

educational setting (e.g., Shernoff et al., 2003), as well as engagement in work settings (e.g., Eisenberger et al., 2005; Sexton, 2005).

Because flow is necessarily a subjective experience, the quantitative measurement of flow has evolved over time. Moneta (2012) provides a comprehensive historical overview of how methodologies to measure flow developed in the literature over the preceding decades as investigation into flow has advanced from primarily qualitative modes of inquiry to quantitative. In addition, this piece provides an introduction to the most common instrument used in quantitative flow research: the *Experience Sampling Method* (ESM). The ESM involves repeatedly assessing individuals with a questionnaire over a period of time in order to contemporaneously record subjective experiences as well as contextual factors. Flow is achieved when two subjective preconditions are satisfied: high skill and high challenge. The ESM utilizes question stems such as "Indicate how you feel about the main activity" and then presents a nine-point Likert scale to indicate 'challenge of the activity' and 'your skills in the activity' in order to ascertain the activity's relative skill and challenge as perceived by the respondent. The ESM also typically includes additional questions such as "Was this activity interesting?", "How well were you concentrating?", "Did you feel like you were in control of the situation?", and "Were you living up to your expectations?" The responses to these questions are used to assess the quality of other subjective states with which flow is positively associated. Empirical studies of the occurrence of flow in educational settings consistently show that flow is associated with the expected correlates, including sense of control, high concentration, and living up to the expectations of oneself and others (e.g., Shernoff et al., 2003). Hektner et al. (2007) provide a detailed explanation of the design and implementation of ESM studies as well as a comprehensive presentation of technical issues related to measuring flow.

Just as a student naturally gravitates toward academic subjects and tasks that offer a higher propensity for experiencing flow, the flow theory predicts that a worker will be most engaged when partaking in occupational tasks that match both high skill and high challenge. Adults who work fulltime are more likely to experience flow during work activities rather than leisure activities and this finding holds across a wide range of occupational levels and professions (Csikszentmihalyi and LeFevre, 1989; Delle Fave and Massimini, 2005; Sartori et al., 2009). Flow is more readily achieved at work than at leisure. Studies consistently find that flow is not associated with elevated levels of enjoyment and excitement observed in studies of recreational activities. This finding is often referred to as the *work paradox* (Csikszentmihalyi and LeFevre, 1989; Csikszentmihalyi, 1997; Hektner et al., 2007). A number of hypotheses to explain this unexpected finding have been put forth. For example, it has been observed that work tasks center around obligations rather than activities of one's choosing and the loss of sense of control may prevent a worker from experiencing flow (Csikszentmihalyi and LeFevre, 1989). In addition, it is also possible that workers often possess a below average interest in the activity, which interferes with the opportunity to achieve flow despite a task's presentation of high skill and high challenge (Haworth and Hill, 1992). Finally, psychologists of happiness have simply noted that while goals are integral to completing work, they also are often negatively associated with happiness (Rheinberg et al., 2007). For a more comprehensive summary of the literature examining the work paradox phenomenon see, Della Fave et al. (2011).

Other recent flow research indicates that flow is sensitive to contextual or situational factors rather than dispositional. For example, Fullagar and Kelloway (2009) used a hierarchical linear model (Raudenbush and Bryk, 2002) analysis of data from an ESM study to show that about two-thirds of the variance in flow experiences is due to situational factors rather than some personal characteristic or disposition. In addition, by analyzing lagged data they found that flow was predictive of mood, but that mood was not predictive of flow. This distinction is important for vocational psychologists in that it suggests that making workers happier probably will not make them more engaged; rather, more engaged workers tend to be happier (among other positive affective states that an employer would prefer). Similarly, Nielsen and Cleal (2010) found that relatively stable aspects or characteristics of different jobs are not as strong predictors of flow as contextual or situational factors. Demerouti (2006) demonstrates that job characteristics could be predictors of flow as well as performance, but only for conscientious workers, which suggests that an individual's relative conscientiousness may be a moderator for the experience of flow.

The theoretical framework of flow has been applied to test the hypotheses advanced by Kohn and Schooler (1982) that there is a strong relationship with a worker's satisfaction with tasks during the workday and the emotional states that they experience at home. Specifically, the construct of flow has been utilized to test the hypothesis that characteristics of work tasks such as autonomy and intellectual challenge strongly influence the subsequent emotional experiences of the worker at both work and home. This finding corresponds to flow theory in that engagement is determined by a match between high skill and high challenge which is positively associated with subjective states such as a sense of control, interest in the activity, and enjoyment (Sexton, 2005). A key distinction in work tasks is made between primary work activities and secondary work activities, where the worker generally prefers the former to the latter. For the most part, workers seek to maximize the time they spend engaged in their primary activity – while minimizing the time spent engaged in less preferred activities, a condition one could identify as indicative of task value expectancy theory.

Among some social psychologists today, it appears that vocational preferences and values are regarded as less about the personality traits of the individual and more about the individual's experiences and the values he or she attaches to those experiences. It is the repetition and value of experiences, influenced in part by social contexts of the family, peer group, and others that determines career interest, motivation, and expectancy.

Conclusion

The application and integration of insights from educational and social psychology has propelled a secular trend in

vocational psychology toward seeking to understand how the workplace stimulates the worker's overall subjective well-being. Indeed, the growing prominence of positive psychology within the practice of clinical psychology has fundamentally changed the purpose of vocational psychology from a model of matching static preferences to understanding the dynamics of how worker preferences and workplace characteristics form and evolve. The increasing rate of technological innovation in the modern world necessitates that employees as well as employers each endeavor to be more fluid in satiating the emotional well-being of workers in order to maximize their productivity and tenure. The challenge for the next generation of vocational psychologists will be to provide the necessary apparatus to facilitate the realization of workers' avidity toward personal fulfillment.

Vocational Training

Núria Rodríguez-Planas, IZA – Institute for the Study of Labor, Bonn, Germany

Abstract

The objective of this article is twofold: first, it reviews the theoretical justifications for the existence of vocational education and training (VET); and second, it summarizes the empirical evidence. After discussing the major empirical identification problems, this article presents international evidence concerning the answers to the following questions: Is VET as effective as general-based education? What are the effects of postponing the tracking of students into vocational schools? Which type of VET best prepares workers for the labor market? What are the returns to a year of apprenticeship training? What is the life-cycle impact of VET? Is informal VET effective? The article concludes with a discussion on policy implications.

Introduction

Vocational education and training (VET) – sometimes also called technical and vocational education and training – refers to qualifying education paths that provide individuals with occupation-specific knowledge and practical skills, independent of the place, content, and education provider. This article focuses on the issue of *initial* VET as in Eichhorst et al. (2013) and Zimmermann et al. (2013), and in contrast to vocation-specific education and training as part of life-long-learning–reviewed, as in Arulampalam et al. (2004) and Bassanini et al. (2005).

VET can be classified into three distinct systems: (1) school-based; (2) a dual apprenticeship system combining school training with a firm-based approach; and (3) informal-based. School-based VET provides youths with a combination of general and occupation-specific knowledge, offered either at the lower or upper secondary level. Accordingly, it is integrated in compulsory schooling as alternative to an academically oriented schooling track, or as part of several postcompulsory education options. Similar to academic education, the skills provided by vocational schools are mostly general given their transferability between employers (Becker, 1964). However, there might be differences in the degree of transferability across occupations – while the VET system in some countries transmits skills that are not restricted to one particular occupation, in others it provides vocational schooling for specific types of occupations (Shavit and Müller, 1998).

Dual VET aims to combine general, transferable skills acquired during class-based VET with structured on-the-job learning and actual work experience within a training company. Apprenticeship graduates acquire occupation-specific skills that render them employable by the training company or other employers, while the overspecialization and low levels of transferable skills generated by the higher share of firm- and occupation-specific training is counteracted by standardized curricula and examinations.

Finally, occupational knowledge is transmitted between generations, within a family or clan in 'traditional apprenticeships' in India and many African countries. Moreover, 'informal apprenticeships' are frequently open to apprentices not belonging to a family or clan. Despite taking place in the informal sector, they have some locally standardized structures and duration, and are based on some contractual agreements between the craftsman and trainee. Apprentices receive no or little remuneration during the training period, and might even have to pay a fee to the trainer. While the training is generally entirely work-based, it may follow an informal training plan. Given the lack of a legal framework to enforce certain training standards, the informality of training may also bear certain risks to the trainee, with particular concerns involving the potential exploitation of children as cheap laborers, gender discrimination based on traditional gender roles, and unenforceable contractual agreements resulting in low training quality or an extension of the apprenticeship duration (ILO, 2011, 2012).

Theoretical Justification for VET

Why Do Governments Offer School-Based Vocational Training?

The government's supply of VET through the educational system can be justified as a means of improving the opportunities of youths who lack the skills demanded in the labor market, or the ability or motivation to continue with higher education (Quintini and Martin, 2006; OECD, 2010a, Middleton and Adams, 1993). Furthermore, individuals might prefer this option to academic education as it implies shorter investment of human capital and facilitates earlier entry into the labor market. Indeed, the close link to work tasks and hands-on-practical experience might represent a source of motivation for practically oriented youths to continue training and remain in school longer, increasing their chances of attaining skilled employment (Shavit and Müller, 1998).

VET is also seen as an instrument to improve labor market mismatch, given that it, ideally, aligns the initial education more closely to particular vocations and tasks demanded by employers. As highlighted by Almeida et al. (2012), the problem of mismatch is often seen as a main source of the high degree of unemployment in developing countries. In such countries, the education of youths with practical-oriented vocational skills is further considered a promising means to create flexible and self-responsible learning attitudes, which might thus better prepare youths for the requirements of the modern work place. Furthermore, given that poor skills and hence the low productivity of firms is often seen as the reason for low levels of development, the investment in vocational

education is often justified as a means to promote a bottom-up labor market transformation. Therefore, the installment of an efficient vocational education system is conceived as an important pillar of the transformation into a knowledge-based economy (King et al., 2007; King, 2011).

In most cases, participation in either vocational or academic courses during school is operationalized by tracking students into the two different education pathways. However, the benefits of such a tracking system are not clear, given that leaving school with vocational qualification often translates into reduced options of further postcompulsory education, and particularly of the academic type. Accordingly, the incentive effect of learning more practice-oriented skills might be mitigated by high costs of later switching to academic education. Although the technical possibility of transferring to academic education might exist, earlier tracking will lead to strongly divergent levels of skills and competences (Woessmann, 2008). Furthermore, through the separation of high- and low-type students, VET might counteract the equalizing potential of vocational education (Shavit and Müller, 2000). Given that only few youths practically manage to enter academic education after vocational schooling (Kogan, 2008), this option is often perceived as a dead-end track and second-choice education for poor academically performing or at-risk youths (Neuman and Ziderman, 1999), and a 'safety net' for early school dropouts and those who are less academically inclined.

In addition, many have highlighted problems with school-based training systems (Woessmann, 2008; CEDEFOP, 2008; among others), with one of the biggest challenges facing school-based VET involving the adaptation of training curricula to the perpetual technological changes of the labor market. Indeed, failure to do so leads to educational mismatch early in workers' careers. The adaptation of school-based education crucially depends on continuous and accurate labor market feedback, as well as the tight coordination among all stakeholders (government, employers, social partners, and educational institutions) in the development and updating of the relevant curricula, as explained by Eichhorst et al., 2013.

Why Would Firms Invest in General Training?

Some of the problems associated with purely school-based training systems, such as skill mismatch, might be solved by the dual VET, given that firm-based training should naturally level off labor supply and demand (Heckman, 1993). Nonetheless, much research has focus on explaining why any employer would provide and finance training. As noted by Becker (1964), while some share of general schooling is crucial in enabling apprentices to enter further employment relationships, firms in a perfectly competitive labor market where workers are paid according to their marginal productivity have no incentives to invest into general schooling, as workers can leave directly after the training period and reap all the benefits of their general skills acquired. Therefore, in order for firms to provide both specific and general training, the cost of general training has to be borne by the worker, which could be implemented by providing either state-funded school-based general education (as discussed earlier) or firm-based general training with workers paying for their training costs. Furthermore, firms could be incentivized to participate if they were able to recoup part of their investments by contractual arrangements ensuring that apprentices accept a wage lower than their marginal productivity during their training period, or if they are able to tie apprentices to the firm beyond the training period (Becker, 1964; Malcomson et al., 2003).

Based on the empirical finding that firms in some countries (such as Germany) invest in general training despite incurring a net cost during the training period (Dionisius et al. 2009), several theories have attempted to explain the training activities of firms (see Wolter and Ryan, 2011 for an excellent overview). In particular, Katz and Ziderman (1990) build a framework in which informational asymmetries regarding the abilities of workers and the quality of training received can lead to sufficient incentives for firms to invest in general training. Alternatively, Acemoglu and Pischke (1998) build an asymmetric information model in which the employer gains monopsony power through learning about their worker's ability during the training period, which incentivizes the employer to offer and pay for training. (In economics, monopsony implies a market form in which only one buyer interfaces with many sellers.) Furthermore, Acemoglu and Pischke (2000) highlight the existence of external certification as a signal to prospective employers that the trainee is willing to invest in their own training. Moreover, Dustmann and Schönberg (2012) discuss that the dual apprenticeship system is likely to be more successful in countries where firms can credibly commit to the provision of training during the apprenticeship, through apprenticeship regulation and external accreditation.

Another set of models aims to explore the deterring effect of poaching, which implies that firms that do not invest in training might hire apprentices from the training firm by *offering* slightly higher wages. Accordingly, several models investigate this hypothesis by exploring exogenous differences in the competition for dual training leavers. Indeed, if firms are able to enjoy some monopsony power arising from industry- and occupation-specific skill requirements, dispersed regional location of firms and lower product market competition, they are found to be more likely to engage in training (Lazear, 2003; Smits, 2007; Gersbach and Schmutzler, 2006).

Empirical Evidence

Identification Problems

Is VET as effective as general-based education? Which type of VET best prepares workers for the labor market? What are the returns to a year of VET? These are some of the questions that researchers have attempted to answer in respect of different countries, as discussed below. As will become apparent, there is no easy answer to these questions given variation both across and within countries across studies. While some such differences are explained by countries' institutional and cultural differences, as well as the available amount of information on workers, jobs, and labor market characteristics in the different data sets used, several identification problems within this literature are difficult to overcome.

Most of this literature compares the employment outcomes of VET students with an alternative group, namely general-based education students or school dropouts, in the same country after controlling for all observable characteristics available. Moreover, it is acknowledged that unobserved heterogeneity may still prevail, given that youths deciding to study VET may have different abilities, tastes, and preferences about work from those who choose an alternative education system or no education. If there are unobserved quality differences between both types of youths, results from cross-sectional studies will reflect an omitted variable bias. For instance, given that VET is frequently intended for youths with lower motivation and ability than those who pursue general-based education, noncausal estimates of the returns to vocational education relative to general-based education will be downward biased (Willis and Rosen, 1979; Tuma, 1994; McCormick et al., 1995). By contrast, the opposite is likely to be true when comparing students from vocational education to school dropouts. Furthermore, a related concern arises due to different occupations requiring a different mix of academic or practical skills. If youths self-select into different occupations based on their skills, evaluating the effectiveness of the different systems becomes a difficult task given that the employment patterns, payment structures, and union coverage in the occupations themselves may not be comparable.

Unable to exploit exogenous changes in the institutional setting, the majority of these country studies conduct descriptive analyses controlling for students' characteristics to capture the expected opportunity of the alternative forms of schooling, including grades and test scores achieved prior to accessing VET or remaining in general education, family background, and local economic conditions. Additional confounders include subjective statements of preferences for VET or academic studies (Bishop and Mane, 2004), subjective self-assessments of ability (Hotchkiss, 1993), and information concerning the vocational orientation of the school captured by full-time vocational teachers and the schooling choice of previous cohorts (Meer, 2007).

In addition to those problems aforementioned, one has to add measurement problems in studies comparing the effectiveness of two types of VET systems across countries. Indeed, cross-country studies analyzing the relative effectiveness of school-based VET and the dual system are frequently biased due to the covariation of other relevant institutional factors, the absence of a unified framework for defining the respective training options, and the difference in data collection and quality (Hoeckel, 2008). While studies exploit the coexistence of the two systems within countries to evaluate their relative effectiveness in an attempt to avoid this problem, nonetheless, as explained by Eichhorst et al. (2013), in most countries one system prevails over the other, with the reason behind this likely to be correlated with the labor market structure, thus adding yet another source of endogeneity.

One way to address the selection problem is to exploit some exogenous change that lengthens or shortens one educational system versus the other. For instance, several researchers have exploited institutional changes increasing the duration of general schooling in the vocational schooling tracks of those respective countries (Oosterbeek and Webbink, 2007; Pischke and von Wachter, 2008; Hall, 2012), whereas others have used an instrumental variable approach (Fersterer et al., 2008). Furthermore, an alternative way to address the endogeneity is to use propensity score matching to address the selection problem (Aedo and Nunes, 2001; Aedo and Pizarro, 2004).

Evaluating School-Based Vocational Training versus General-Based Education: Which One Works Best?

Evidence from the US indicates that, once selection into VET has been accounted for, its participants perform equally or better than high school graduates in terms of employment and wages, also suggesting that these returns have increased over time. For example, Hotchkiss (1993) investigates the short-run effects of vocational schooling on employment and wages of high school graduates in 1980, finding no returns to vocational schooling even after controlling for training-related occupation choice. In contrast, Bishop and Mane (2004) and Meer (2007) investigate the short- to medium-run effects of participating in technical schooling among high school graduates in the US during a longer time period. While the former find youths to greatly benefit from choosing the vocational schooling track both in terms of employment and wages, Meer (2007) finds positive yet small wage increases, with these differences explained by using a more elaborate selection equation. Furthermore, Mane (1999) assesses differences in returns to technical schooling between the 1970s and 1990s more systematically, confirming this positive trend during the 1980s and 1990s.

In contrast, evidence in the UK reveals that academic education leads to higher returns, with Robinson (1997) finding that this is partly explained by academic jobs providing access to better paid occupations. Presenting evidence that lower ability and family background are also important drivers behind lower levels of education in the UK, Dearden (1999) casts doubt on the causality of these earlier findings. Reassessing the earlier findings, Dearden et al. (2002) largely confirm that academic education leads to higher returns, while finding significant heterogeneity regarding the type of VET obtained. In particular, they find that the majority of vocational education programs increase earnings relative to no vocational qualification, especially for low-achieving school-leavers. However, one exception is the UK's National Vocational Qualification (NVQ2), a VET course often undertaken during employment, which seems to have a negative impact on the wages of individuals, and even relative to those with no other qualification (Dearden et al., 2004).

Findings from early studies in developing countries are mixed (see the review by Chung, 1995). For instance, while Psacharopoulos (1994) finds that the returns to vocational secondary education are lower than those from general education, using evidence from 24 countries, when combining data from Psacharopoulos (1994) and Psacharopoulos and Ng (1992) for Latin American and Caribbean countries, Bennell (1996) finds that the differences in both systems' rates of returns are relatively small. According to Bennell and Sergerstrom (1998), and Middleton and Adams (1993), the effectiveness of vocational skills depends on the local demand for labor in the private sector and individuals' ability to find employment in the occupation of training. While most recent studies addressing the selection into VET problem remain

mixed, they seem to indicate that the differences in results lie in the institutional settings (such as the flexibility of labor market regulations) and historical and cultural differences with respect to the organization of work processes (see Almeida et al., 2012; for a thorough literature review in developing countries). For instance, Kahyarara and Teal (2008) investigate the returns from vocational education tracks in Tanzania, finding that the continuously strong preference for academic education is driven by the extremely high returns to high levels of academic education. Furthermore, they also show that lower levels of academic education and vocational education have very similar returns, suggesting that the convex return to education is at least partially driven by the selection of highly educated individuals into large, high-paying firms. Moenjak and Worswick (2003) compare the returns to the two vocational and academic tracks at the upper secondary level in high schools in Thailand, where both tracks qualify individuals to enter higher tertiary education. Moreover, when controlling for positive self-selection using a Heckman selection correction, their results point to a higher return to vocational education. Newhouse and Suryadarma (2011) analyze the returns to vocational versus academic high school tracks in Indonesia, with their results on labor market returns suggesting a change in the returns to vocational education over time. They find significantly higher wage returns for older cohorts yet lower returns for younger cohorts, explained by the decreasing value of vocational skills in the increasingly service-oriented Indonesian economy. Tansel (1994, 1999) and Tunali (2003) provide evidence for the returns to vocational high school education in Turkey, suggesting that the vocational tracks outperform academic tracks in terms of wages for men, and employment probabilities for women.

The Effects of Postponing Tracking of Students into Vocational Schools

Some studies have measured the effects of postponing tracking or extending general human capital education by exploiting exogenous policy changes increasing the duration of general schooling in the vocational schooling tracks, and overall do not find large (if any) effects of such policies on students' wages or employment probabilities. Oosterbeek and Webbink (2007) investigate the increase in duration of the vocational schooling track in the Netherlands in 1975 for 1 year, with the additional year designated only to general schooling. Adopting a difference-in-difference strategy, they analyze the effect of the change on wages 20 years later, and do not find any effect. Similarly, Pischke and von Wachter (2008) exploit the gradual adoption of a 1 year increase in compulsory schooling in the lowest schooling track in Germany between the 1950s and 1970s to study its effects on long-term wages, and likewise find no effects of the policy. Most recently, Malamud and Pop-Eleches (2010) evaluate a Romanian reform that postponed the tracking of students into vocational and academic schools. Using a regression discontinuity design, they find no effects of this reform on university completion, labor market participation, or earnings. While these previous studies consider extensions of general schooling at the lower secondary vocational tracks, Hall (2012) assesses a policy change in Sweden in 1991 that increased the general education content of the vocational schooling at the upper secondary level by 1 year in duration, after which students were eligible to enroll in tertiary education. Exploiting random differences in time and the regional implementation of a policy pilot, Hall (2012) does not find any effects on subsequent study take up, nor any increase in the wages earned up to 16 years after the beginning of upper secondary school. However, he finds that low-achieving students are significantly more likely to drop out of upper secondary education.

Dual System versus School-Based System?

While studies that have exploited the coexistence of the two systems within countries to evaluate their relative effectiveness find that, once selection is accounted for, the dual system seems to offer an advantage of improving early labor market transitions (measured in a variety of ways), evidence seems to indicate that these benefits eventually fade away. For instance, studies by Winkelmann (1996) and more recently Parey (2009) using German data show that participation in the dual apprenticeship improves early labor market attachment and leads to a faster and more structured integration into the labor market, relative to school-based VET. However, these short-term benefits fade away as other education participants find a foothold in the labor market. Moreover, Parey (2009) does not find any significant wage differences across the two types of training.

Similar results on the performance of apprenticeship training versus school-based training are found in studies by Bonnal et al. (2002) for France and Plug and Groot (unpublished manuscript) for the Netherlands. Correcting for the negative selection of youths into the dual apprenticeship, both studies find that apprenticeships perform significantly better in integrating youths into their first employment relationship by the higher labor market relation of their training. However, again this advantage is found to fade over time and is not associated with higher wages. A recent study by Alet and Bonnal (2011) shows that young people integrated into the dual apprenticeship system rather than vocational schooling in France are more likely to successfully complete their final exam and undertake further education.

In countries where the dual apprenticeship is not considered a 'trainer of last resort' for lower skilled individuals, the apprenticeship system is also found to partially act as a mechanism to level the playing field for youths with low school performance. Exploiting information on Programme for International Student Assessment (PISA) test scores to capture differences in ability across students, Bertschy et al. (2009) show that lower performing youths in Switzerland tend to select into less demanding apprenticeship occupations and are thereby penalized in the labor market; however, their initial test score (as a signal of their ability) is no longer important in determining labor market outcomes.

Estimating the Returns to VET Programs

Rather than comparing two systems within a country, several studies have analyzed the returns to apprenticeship training in a particular country. However, selection into this vocational training system and the different types of apprenticeship once

again raises concerns that Ordinary Least Squares (OLS) wage estimates will be biased (Soskice, 1994). In particular, Soskice finds that much heterogeneity is due to firm size, given that the wages for apprenticeship-trained workers increase strongly in the size of the training firm. Several papers have found that the wage returns to apprenticeship training on wages in Germany and Austria range between 15 and 20%, based on OLS estimates (see Krueger and Pischke, 1995; Winkelmann, 1996; Fersterer and Winter-Ebmer, 2003). Given that an apprenticeship lasts around 3 years on average, this implies a return of around 5% a year, which is not far from other forms of school-based education, in colleges or vocational schools. One of the first studies to use an instrumental variables approach to measure the returns of apprenticeships is that of Fersterer et al. (2008), using Austrian data from 1975 to 1998. These authors exploit the different length of apprenticeship period completed for some apprentices in failed firms, and perhaps surprisingly find that the estimated returns for apprentices affected by the firm failure are not very different from the OLS returns in the same sample, suggesting that selection problem is not particularly important in this case.

The Life-Cycle Perspective

A recent line of research has focused on studying the life-cycle impact of vocational education, motivated by the returns to vocational training potentially being quite different at labor market entry than after several years into the labor market, given that skills have to adapt to technological change and be mobile across firms, occupations, and space. Hanushek et al. (2011) use data on the labor market experiences of people at different ages and in 18 different Organisation for Economic Co-operation and Development (OECD) countries, collected in the mid-1990s as part of an OECD-sponsored venture, to compare the life-cycle employment patterns of people with different educational backgrounds. They find a higher initial employment rate for vocational education participants at labor entry, which is reversed by the age of 50, and these results are suggestive of the hypothesis that occupation-specific knowledge outdates faster and thus leads to lower employment opportunities later in life. At the same time, they also find that this pattern is more significant in 'apprenticeship countries' with combined school and work-based education programs (Denmark, Germany, and Switzerland in our data), as opposed to countries with no formal system of vocational education, such as the US. However, more reliable evidence is required concerning the perceived trade-off, given that the causal interpretation of these findings is impeded by occupation-specific segregation of the labor market and the limited availability of long-term panel data.

Alternatively, another recent study by Adda et al. (2011) models the entire career path, starting with the original apprenticeship choice and followed by the period-by-period employment transitions, job mobility, and wages. A structural approach is used to take the dynamics over the life cycle into account, since the two career paths may differ in job attachment, available job opportunities, and wage growth. Using 15 years of German data, they find that apprenticeships lead to more wage growth up front, while wages in the pure on-the-job training (unskilled) grow at a lower rate yet for longer. Overall, they find that wages are higher following an apprenticeship qualification, with the job arrival rates very high and destruction rates very low after some years of experience. These findings contrast with Heckman's suggestions that qualified apprentices are harder to reallocate following a job loss (Heckman, 1993).

What Is the Evidence on the Effectiveness of Informal VET?

Evidence on the effectiveness of informal training is clearly scarce, given that it mostly pertains to developing countries, and also owing to the nature of the training per se, which relies on the informality of both the labor market and training. Nonetheless, the few identified studies inform on the selection problem observed for the other types of training, and seem to indicate that informal training improves trainees' labor market opportunities. However, further research on evaluating traditional and informal apprenticeships is needed.

Compared to informal jobs without training, the informal types of VET are considered to improve the chance of achieving promotion inside informal businesses from unskilled to skilled worker, consequently earning a higher wage. Accordingly, training is essential to become a master craftsman and set up or take over a business in these fields after some years of activity (Aggarwal et al., 2010; Nübler et al., 2009). Furthermore, compared to vocational schooling, which often relies on outdated curricula and lacks the involvement of employers in many developing countries, informal and traditional apprenticeships are coupled with current skill demands and work practices in the informal sector, with informal apprenticeship graduates more easily employed than those from vocational schools. Given that they do not require any formalized entry criteria, informal training often represents the only opportunity for school-leavers to obtain vocational education (Walther, 2011).

In terms of labor market outcomes, evidence from studies on Malawi and Tanzania suggests that most graduates from informal apprenticeships were employed with the same business that had provided training, or with some other employer, with a considerable share of them also being self-employed after some years (Aggarwal et al., 2010; Nübler et al., 2009). Furthermore, an evaluation study of the informal apprenticeship system in Ghana shows an important negative selection of youths into informal apprenticeships, involving youths with low levels of general schooling entering this type of training (Monk et al., 2008). However, when controlling for this negative selection, it is found that individuals with low levels of formal schooling substantially benefit from the informal training, with earning increases of 50%.

Conclusions and Policy Implications

VET represents a valued alternative beyond the core of general education, with the dual system seeming to be more effective at facilitating labor market entry than school-based VET, although this advantage seems to fade over time. While informal training

is effective, not much is known concerning its relative strengths compared with other forms of vocational education.

As explained by Eichhorst et al. (2013) strengthening the vocational part of the educational or schooling system and bringing existing VET systems closer to the current needs of the labor market would help young people with a smoother transition into work in many countries. In particular, vocational education provided in the framework of secondary schooling (vocational schools or vocational tracks) should be modernized and complemented with phases of practical work experience, such as internships or passing the final year with an employer. Employers should also be consulted regarding the design of vocational schooling curricula, which requires a systematic coordination with networks or associations of employers. Furthermore, in order to avoid a negative perception of vocational education as a dead-end option, transition to further education, including tertiary education, should be facilitated. Finally, reducing vocational education fees can help to raise enrollment in some countries. Moreover, in countries with high shares of university graduates facing major difficulties in finding adequate jobs, one significant option is to make academic training more labor market-oriented, incorporating internships with employers into academic curricula to enable the attainment of some experience with current work practices in the private sector. Governments responsible for funding academic education can require public universities to modify academic curricula accordingly.

Providing better training for the informal sector represents a core issue for many developing countries. In countries where traditional or informal apprenticeships are dominant yet mainly confined to traditional crafts, they should be better articulated with the schooling system and formal sector, and also open up to new technologies and occupational change, which requires some recognition of informal employment as part of the economic and social reality in many countries. One first option is to bring societal initiatives aimed at better training closer to the informal sector, family business, and local networks. Accordingly, a concrete step could involve encouraging informal workers and employers to participate in training activities, such as providing informal apprentices with some vocational schooling focusing on more general skills and theoretical aspects. The participation in vocational courses of young people working in the informal sector could be increased by providing incentives to both participants and employers, particularly compensating for hours not worked due to training courses. Moreover, to avoid deterrence, these courses should not be delivered directly by governments, but rather by NGOs, churches, or nonprofit associations with sufficient acceptance and in-depth knowledge of the economic situation in local communities. Involving larger employers or (formal) training centers represents another option, with funding potentially coming from governments and international donors. Furthermore, NGOs, churches, or other nonprofit associations can also facilitate the creation of (informal) associations or networks of informal employers.

Given that traditional or informal apprenticeships tend to be restricted to a number of traditional crafts, raising productivity and potentials for innovation is crucial. Experiences from the African continent show that master craftsmen benefit from skill-upgrading courses to better develop their businesses and become more innovative and productive, and also from better access to technical equipment and capital, which should be made more easily accessible to informal firms. Furthermore, some experiences from sub-Saharan Africa show that ensuring skill recognition outside the local community through some sort of official skill testing open to informal apprenticeship graduates raises the attractiveness of such training courses and enhances mobility on the job market.

Abstract

Voluntary organizations have two main subtypes: voluntary associations and voluntary agencies. This article deals with voluntary associations, whereas a different article entitled 'Voluntary Organizations' deals with voluntary agencies. This article reviews association governance and leadership, history, prevalence rates and their determinants, purposive, and analytical types of associations, geographic scope, degree of paid staff dependence, targets of benefits (recipients), types of members, formalization and government recognition, misconduct and deviance in and by associations, government control issues, internal democracy, monomorphic and polymorphic associations, collaboration, intensity of activity, personal contact and relationships, membership requirements, prestige and power, and degrees and types of impact.

According to *Merriam-Webster's Unabridged Dictionary*, the word 'voluntary' means an action of a person's (free) will or choice. Voluntary organizations (VOs) fit with this definition by being organizations that people join and participate in by their own free choice, not because of compulsion by law or force. By common definitions (e.g., Smith et al., 2006), VOs are distinctive in having not-for-profit (nonprofit) primary goals, as contrasted with business organizations (businesses), which have for-profit primary goals. There are various other common names for VOs, the most frequent being nonprofit organizations (NPOs), nonprofits, nongovernmental organizations (NGOs), and civil society organizations (CSOs).

There are two main structural types of VOs: associations and nonassociational nonprofits (Smith, 2000: p. 30). Nonassociational nonprofits, usually called voluntary agencies or nonprofit agencies, are treated in a different article in this *Encyclopedia*, under the title, voluntary organizations. The present article discusses voluntary associations, often simply called associations (or sometimes membership associations).

Many people confuse voluntary associations and voluntary agencies, or incorrectly use the term voluntary organizations to refer just to *one* type or the other, not to *both* as is correct. Others similarly fail to understand how different the two basic VO types are in their basic structure. Simply put, voluntary associations have a structure in which there are members who usually hold the ultimate power, whereas voluntary agencies usually have a board of directors (or trustees) that holds the ultimate power. Voluntary agencies (sometimes called social agencies or welfare agencies) have no members, but they do have paid staff and often volunteers working in volunteer programs as VO departments. Quarter et al. (2001) have shown empirically that membership associations are distinctive in many important ways from nonmember-serving voluntary agencies.

In an association, members usually elect the top leaders (board members, officers) on a regular basis (e.g., annually, biennially, etc.). In a voluntary agency, the board of directors (trustees) is usually self-perpetuating, electing, or appointing new members as needed, sometimes annually or biennially. There is no category of members as a kind of agency affiliate, just employees and often volunteers, as noted. In sum, voluntary associations usually practice a kind of internal democracy, while voluntary agencies rarely if ever practice internal democracy. Voluntary agencies generally are structured more like government agencies or business corporations, as hierarchical bureaucracies with the power at the top. This crucial difference in basic internal structure makes these two subtypes of VOs very different in their operations, organizational culture, resource attraction processes, and impact on participants, among many other effects (Smith, 2000: Part 2). Smith has argued that these two VO subtypes constitute different subsectors of the voluntary nonprofit sector (VNPS), third sector, or civil society sector (Smith, 1991).

Research and Theory about Associations

Research on associations, in the form of historical accounts, goes back at least three millennia, perhaps four to five (Kloppenborg and Wilson, 1996; Smith, 1997). Quantitative empirical research by social scientists began very recently, in the early middle of the twentieth century (Smith et al., 2014: Chapter 1; Smith and Associates, 2015). *Organized* research on associations and other VOs began in 1971, with the founding of the Association for Research on Nonprofit Organizations and Voluntary Action (ARNOVA) and its journal, *Nonprofit and Voluntary Sector Quarterly* (Smith et al., 2014: Chapter 1). Many similar associations of researchers and additional academic journals on VOs and on related phenomena of the VNPS subsequently have been founded (Smith, 2013). Another global and interdisciplinary association of researchers was founded in 1992, named the International Society for Third Sector Research (ISTR; Smith, 2013).

The website (ICSERA) of the International Council of Voluntarism, Civil Society, and Social Economy Researcher Associations (ICSERA) lists and updates information on all known researcher associations, academic journals, and research centers in the field (and emerging academic discipline) worldwide. ICSERA is an umbrella association of other researcher associations studying the VNPS, mainly national associations. ICSERA seeks mainly to help build the organized, global research field (and emerging academic discipline) of VNPS research, now termed 'voluntaristics' or 'altruistics' by Smith (2013).

The most comprehensive book summarizing recent research and theory on associations is the *Palgrave Research Handbook*

of Volunteering and Nonprofit Associations (Smith et al., 2014). Contributors from more than 70 nations and all world regions review and assess research on most relevant topics regarding associations and volunteering in associations in 61 chapters and an appendix, including chapters on theory and methodology for studying associations and volunteering in associations. There is no widely accepted general theory of associations, although Smith (2000) has presented an extensive theory of grassroots associations (GAs; see Smith, 2010a). Some middle-level theories are focused on individual volunteering in associations (Smith et al., 2014: Part IV), association prevalence (Smith et al., 2014: Chapter 36), and deviant voluntary associations (DVAs; Smith et al., 2014: Chapter 59).

The History of Associations

For most of the period of existence of our human species (about 150 000–200 000 years), there were no VOs. All societies were small, nomadic, hunting-gathering bands of about 40–70 people, which had no subgroups other than nuclear families of parents and children. The earliest VOs were voluntary associations, originating perhaps 25 000 years ago. Such associations became common about 10 000 years ago, when most human societies had settled down in agricultural villages that had an average of 1500 people, so that subgroups now made sense (Smith, 1997).

For several millennia, associations were mainly social clubs, especially for adult males (Smith, 1997). In ancient agrarian civilizations like Greece and Rome, occupational associations as guilds were added to social clubs as a type of association, as were religious associations (Kloppenborg and Wilson, 1996). Early Christian churches in the Roman Empire were examples of the latter, as were much earlier Egyptian and Greek religious cults (Boulding, 1953; Smith, 1997).

In the second millennium AD/CE, many new types of associations arose, especially in the past two centuries as a result of the Industrial Revolution (Boulding, 1953; Smith, 1997). There has also been a tremendous increase in the numbers of associations in this recent 200-year period – an organizational revolution and especially an associational revolution (De Tocqueville, 1976; Smith, 1997, 2010a).

The Prevalence of Associations and Its Determinants

If the prevalence (frequency in a territory) of associations is plotted on a historical timeline for the human species, there were none until about 25 000 BC and then significant numbers from about 10 000 BC. This rise of associations resulted from the horticultural revolution, in which much smaller, nomadic, hunting–gathering tribes settled down in still small, but significantly larger (estimated 1500 persons), villages to crudely raise crops and domestic animals (Smith, 1997).

When full-scale agriculture was later discovered *c*.3000 BC in Egypt and China, later in Greece, Rome, and Mesopotamia from 1000 BC to the turn of the millennium, economic surpluses permitted large cities and greater differentiation of occupations beyond farming. This much greater division of labor, especially in cities, created a corresponding differentiation of individual and family interests or goals, leading to the formation of guilds for different occupations as economic associations.

Much later, the Industrial Revolution, beginning about 1800 in the West, gave a tremendous impetus to association prevalence (Smith, 1997). In terms of the noted graph (Smith, et al., 2014: Chapter 36), association prevalence has leapt upward exponentially on a global scale since about 1800. Boulding (1953) has referred to this change as the organizational revolution. More recently, other scholars have referred to it as an associational revolution (Smith, 1997, 2010a). These terms highlight the large and rapid increase in association prevalence in the past two centuries plus, especially in all nontotalitarian nations undergoing modernization. The key changes in social structure that foster rapid growth in association prevalence are industrialization, development of mass education systems, expansion of the mass media, growing democratic participation and civil liberties, and construction of an extensive transportation–communication infrastructure.

Not surprisingly, the absolute (raw) number of associations in a nation or other territory is strongly related to the sheer population size in the area studied. Recent research on the nations of the world, however, has shown that the prevalence of associations per capita (or per 1000 population) among the nations of the world can be explained successfully (89% of the variance) by such additional variables as higher gross domestic product per capita, higher average level of formal education, greater presence of civil liberties (especially freedoms of association, assembly, religion, speech, and mass media), longer national experience with democracy, greater number or density of nonassociational organizations (businesses and government agencies) per capita, and greater resource mobilization fostering associations, such as information, consulting support, and research infrastructure organizations (Smith and Shen, 2002; Smith et al., 2014: Chapter 36).

Purposive versus Analytical Types of Associations

Many scholars and laypeople tend to view the primary or official purpose of an association as its most crucial characteristic. Research does *not* support this view. Far more important are the analytical characteristics of an association, such as the geographic scope of its activity, use of paid staff if any, degree of formalization (bureaucratization), types of members (individual persons as members versus organizations versus both), the target of benefits (members versus nonmembers or both), monomorphic versus polymorphic form, and so on (Smith, 2000). This article is divided into many small sections based on a variety of important analytical types or categories, not based on simplistic purposive types of associations (Smith, 2000: pp. 4–5, 232–233).

The Geographic Scope of Association Activities

Associations exist with the widest range of geographic scope, from truly global international associations that have members from nearly 200 nations and territories, down to GAs having members only from a single apartment building or condominium. With such variations in geographic scope come many

other variations in association structures and processes. For instance, international and national associations tend to be much more formalized than GAs, larger in membership size, meet much less frequently in person (annually or less frequently in conferences, if at all), depend more on electronic (especially Internet) communications, have a longer average life span, have their own rented or owned headquarters buildings and offices, have greater income and assets, collaborate more with other organizations, are better known to the general public, and tend to have more power or influence in their societies (Smith, 2010b; Smith et al., 2014: Chapters 38 and 39).

Degree of Dependence on Paid Staff

Because the vast majority of associations everywhere are GAs, they usually have no paid staff at all, even part time. Associations with larger memberships and at supralocal levels of geographic scope (state/provincial, national, and international associations), however, usually have some paid staff, even if only part-time. Very large associations, such as the AARP (American Association of Retired Persons) in America with nearly 40 million members, have hundreds of paid staff. Thus, there are really two distinct analytical types of associations in terms of their operations: The large majority of associations are led and run by volunteers, as amateurs in informal groups. A small minority of associations has one or more full-time paid staff in more formalized associations, with the paid staff doing much or most of the work of the association. In associations with paid staff, the internal dynamics of the association are changed. Paid staff, especially the top executives, have much more influence than members, and often more than the elected volunteer officers of the association. Member passivity and apathy usually contribute to this tendency for dominance by paid staff.

Target of Benefits

The 'target of benefits' of a group is the set of the people or situations that the group intends to help, protect, or improve in some way. Sometimes associations have clear recipients, but not always. Most associations have their members as the main target of benefits, hence being termed 'member-benefit' groups. Nearly all GAs are member benefit associations.

Some associations, especially national or international associations, have specific nonmembers or the general public as the target of benefits (intended recipients). Nonmember benefit associations may also benefit no specific recipients, as with environmental associations and some political or social movement associations. Also, some associations serve both members and nonmembers. There is altruism or serving others involved in both member benefit and nonmember benefit associations. But in member benefit associations, the altruism is limited mainly to fellow members of one's own association.

Examples of member benefit associations include religious congregations, occupation-focused associations (labor unions, farmers' associations, professional associations, business people's groups, trade associations), self-help groups (Alcoholics Anonymous groups, cancer survivors' groups), social clubs, and indulgent leisure groups (e.g., chess clubs, amateur baseball or soccer clubs, transvestite groups). Some examples of nonmember-benefit associations are political parties or associations, social service associations, social movement organizations, and environmental groups.

This internal versus external focus of associations significantly affects group structure and operations. For instance, member benefit associations depend mainly on member dues (required annual payments by all members) or voluntary member donations for their income. By contrast, nonmember benefit associations receive more donations from the general public, fees for services, and sometimes receive grants from foundations.

Individual versus Organizational Members

Associations may have individual persons as members or organizations as members (collective members), or both. Most associations emphasize one or the other type of members, not both. Associations with individual persons as members greatly predominate at all geographic levels of scope, especially at the local level, as GAs. As examples, the Association for Research on Nonprofit Organizations and Voluntary Action (ARNOVA) has mainly individual persons as members. By contrast, the International Council of Voluntarism, Civil Society, and Social Economy Researcher Associations (ICSERA) has associations of researchers as collective members. And the International Sociological Association (ISA, http://www.isa-sociology.org) has both 45 national sociological associations as collective members and also about 4500 persons as individual members.

Degree of Legal Formalization and Government Recognition

Associations vary markedly in their degrees of legal formalization and recognition. In most societies, the vast majority of associations, as GAs, have no legal formalization at all. Most GAs are thus informal groups. For instance, in the United States and China, there are many millions of unregistered and unincorporated GAs (Smith, 2000: Chapter 2; Wang, 2011). Nonprofit agencies are much more likely to seek and obtain legal and government recognition than are associations, especially GAs.

In most nations, the law requires larger associations in terms of income, assets, or membership to register with the government. Such registration may lead to or provide legal tax exemption for net revenues. Net revenues are 'surplus revenues' after paying expenses, because there are technically no 'profits' in nonprofit groups. In addition, most nations provide for legal incorporation of an association, so that it can become a 'legal person,' able to have its own bank account, hire employees, own real estate, and so on. In some nations (such as China), the legal incorporation and registration processes are merged, handled by a single government agency.

Degree of Internal Formalization of Association Structure

As small, local, volunteer-based associations, most GAs have loose and informal internal structures. Boards of directors are

rare in GAs, although there usually is one or more key officers (like president, vice president(s), treasurer, secretary) elected by the members annually or less often. The group boundaries of GAs may be vague or loose, so membership is not always clear. In some GAs, whoever attends a given event or meeting is a 'member.' Most GAs keep a formal list of members, however, seeking donations or dues from each one if the person is to remain a member in good standing (official member). In larger GAs and supralocal associations ('above the local level' – at the state/provincial, national, or international level of geographic scope), membership lists are usual. In addition, committees (subgroups of members appointed by the leaders) are charged with specific functions, like arranging events, recruiting members, and generating publicity.

Larger GAs and especially supralocal associations tend to have more internal bureaucracy, usually with three or more levels of structure (e.g., members, committees or departments, key officers, board of directors, the top leader as chief executive officer). These formalized associations tend to have a written constitution, bylaws, or other documents stating explicitly how the association will operate. Such increased internal formalization is more frequent in associations with a paid staff, especially a larger paid staff. Some nations (e.g., China) have legal requirements for significant internal structure and assets before an association can gain legal recognition from the government.

Conventional versus Deviant Goals and Means

Most scholars and the general public think only about conventional, mainstream, socioculturally acceptable associations, ignoring the dark side of associations and of the VNPS. But a small minority of associations in any contemporary society (and in most prior societies) has one or more goals, or a means of achieving their goals, that break the laws or moral rules of their society at the time. These are termed deviant nonprofit groups (DNGs; Smith et al., 2006, 2014: Chapter 59). Volunteers usually run associations, especially GAs, and hence GA leaders and members have no association-related paid jobs to lose. As a result, associations, not voluntary agencies, are the more common kind of DNG, sometimes being willing to take great risks collectively and intentionally. Associations that are DNGs may be termed 'Deviant Voluntary Associations' or 'DVAs.' Voluntary agencies, especially foundations, very rarely take substantial risks by any persisting deviance. When deviance is discovered or made public in a voluntary agency, the people involved usually are caught and punished, at the very least by being fired.

Some common types of DVAs include (1) revolutionary, terrorist, and guerrilla groups as violent political DVAs; (2) doomsday cults (ones that commit mass suicide, like the Peoples' Temple), witches' covens, and polygamous sects as religious DVAs; (3) nudist groups, group marriage, and free-love communes as sexual DVAs; and (4) aggressive hate groups (Al Qaeda, the Ku Klux Klan, Skinheads) as violent DVAs. Some DVAs, like the Nazi Party, fall into more than one of these categories. These DVAs range widely in how serious their deviance is. Nudist groups are harmless, but the Nazi Party in the Third Reich, initially just a DVA with revolutionary goals (1921–33), was directly responsible for the deaths of tens of millions of people in the holocaust and World War II (1933–45).

Because of their societal rule-breaking, DVAs usually have to operate secretly or 'underground' to a significant degree. DVAs carefully avoid legal formalization and government recognition, which would lead to greater government control and often dissolution of the association. DVAs tend to hide their headquarters and meeting locations, their membership lists, and their assets, rarely holding public activities to which outsiders (nonmembers) are invited. Political DVAs, however, may hold public rallies to seek new members and financial support. DVAs may obtain some of their income from illegal activities, but such criminal, income-producing activities are *not* central in DVAs, by definition. (When criminal income-producing activities become central to a group, it is a deviant business, like the Mafia, not a nonprofit DVA.)

DVAs are nearly unique in the high degree of risk and danger they involve for their members and leaders. If caught and convicted by government authorities, participants in DVAs may be imprisoned or even executed. Milder negative outcomes may involve large monetary fines; losing one's job, professional credentials, or reputation; and losing one's family relationships or spouse. Members usually conceal their membership in a DVA from other people, even from close friends and relatives, to the extent possible. All this secrecy is needed to avoid being discovered and punished by government authorities. DVAs generate very high, if often temporary, commitment to the beliefs and goals of the DVA. This strong commitment is necessary to counteract psychologically the substantial danger and risks involved when a person is a member of, or actively participating in, some DVA. Unlike most associations, DVAs can become groups a person would die for. This is rarely true of conventional associations, and almost never true for voluntary agencies. Very powerful group ideologies and deep, close personal relationships with other association members and with leaders usually are involved. Such DVAs become 'primary groups,' like families, unlike most contemporary associations being 'secondary groups.'

Degree of Government Control of Associations

The degree of government control over a specific association or type of association varies greatly. All national governments seek some control over associations operating within their geographic territories, especially for larger associations in terms of members, assets, or income. Totalitarian dictatorships usually eliminate or take over direct control of associations when such regimes assume power, often in a military coup or revolution. This was true in Stalin's Soviet Union, the Nazi Third Reich, and in Mao's China. Nontotalitarian but still authoritarian regimes, with very strong and controlling governments, often allow limited numbers of associations to exist with close government monitoring. But in such nations, the government suppresses opposition political associations or parties, as well as political activities by officially *non*political associations.

More democratic and participatory government regimes allow all kinds of associations to form and exist, so long as they do not break specific laws (e.g., involving treason, violence, disorder, conspiracy, harm to people or property, or theft). The

existence of laws or regulations in a nation guaranteeing civil liberties and strong enforcement of these rules leads to many more associations being formed and being active (greater association incidence and prevalence). In these nations, a genuine civil society may be said to exist. Mere presence of a large voluntary, nonprofit sector with many VOs, as in China now, does not by itself indicate a civil society (Smith, unpublished).

In transitional authoritarian regimes (former totalitarian dictatorships) like the Russian Federation and the Peoples Republic of China, there remain many barriers to the formation, government registration, and independent operation of associations (Guo et al., 2012). Such governments fear active political opposition that could be generated by large associations with any stated goals, not just openly stated political goals. For instance, in China nearly all *national* associations are directly controlled by the party-state, although lower geographic scope associations, especially GAs, now often have substantial operational freedom in making their own decisions. In post-Communist Europe, associations and other VOs remain weak 15 years after obtaining official freedom (Howard, 2003). This weakness results in part from lingering government fears of opposition and also public suspicions regarding nonprofits, volunteering, and associations, based on prior negative experiences under Communist regimes.

Degrees of Internal Democracy

Although voluntary *agencies* have little or no internal democracy, voluntary *associations* tend to have more substantial internal democracy. Guo and Musso (2007) have distinguished *formal* representation (fair, contested elections for leaders) from *participatory* representation (mechanisms for members to participate in key decisions). Especially in more democratic nations, the membership in associations usually has a voice in electing their top leaders annually or less often. In societies with less experience regarding participatory democracy and free associations, however, the association leaders in a given year often decide among themselves, by consensus or voting, who the next year's association leaders will be. Thus, associations can vary greatly in their internal democracy, both within and especially among nations.

The more authoritarian the nation's political regime, the more likely an association will be to have a single, autocratic leader (autarchy) or a small set of top leaders (oligarchy) in power over many years. In authoritarian nations, leaders of supralocal associations often are selected by some official of the government, rather than by the membership of the association. In nations with more democratic government regimes and stronger traditions of civil liberties and democracy, associations usually have more substantial internal democracy at any level of geographic scope. Internal democracy in an association can be defined as having *both* the aspect of formal representation as well as the aspect of participatory representation (Guo and Musso, 2007):

1. Formal representation involves such regular processes as the rotation of specific persons in top leadership positions, contested (two or more candidates) elections of top leaders (key officers, board of directors) by all members annually or less often, and term limits on key officers and board members (such as only two terms in a specific position being allowed for any individual). In more democratic political regimes, there also tends to be better representation among the top association leaders and board members of the membership as stakeholders, relative to the situation in more authoritarian regimes. Even in democratic regimes, there is a tendency toward leadership oligarchy in associations, with the same people remaining powerful over long periods of time. Such leaders often move among different key positions or just have informal power, with no official position at present.
2. Participatory representation involves such regular mechanisms as (1) the provision for holding internal town hall (total membership) meetings to discuss and even vote on major issues, (2) special advisory committees (including many members as well as leaders) focused on discussion and decision making on some key issue(s), and (3) leader-recall elections. Such elections, usually based on the constitution or bylaws of the association, include provisions for members to create and sign petitions for recall elections. In the election itself, members may vote to remove or keep one or more, specific, top leaders whom a sufficient number of members perceive as inadequate in their skills or as acting improperly.

Monomorphic versus Polymorphic Associations

Many associations, especially GAs, are unique, with no linkages to similar associations elsewhere in the same nation or different nations. These are termed 'monomorphic' associations (Smith et al., 2006), having only one form. Many other associations, however, especially GAs, are branches (subunits) of some larger, often supralocal, association. These are termed 'polymorphic' associations, having many (poly-) forms or branches (morphs). Such associations are more frequent in the developed, industrial, and postindustrial nations of the Global North. For instance, a local trade union or religious congregation may be part of a state, provincial, national, or even international association. Similarly, a Boy Scout or Girl Guides troop in a given neighborhood is usually part of a city, state, national, and then international Scouting Association (as an international NGO (INGO)).

This analytical distinction is of substantial practical importance: Polymorphic GAs elicit better public name recognition and more positive attitudes from the public, usually have more prestige, are better able to recruit new members and leaders, attract more donations and gifts, and, as a result, live longer. Such polymorphic GAs receive various kinds of help and support from their larger, usually supralocal, parent associations. In addition, polymorphic GAs are usually able to follow established and successful patterns of internal structure and activities. Unlike monomorphic associations, polymorphic associations do not need to invent everything they do, instead following successful pathways and rules or patterns invented by others in similar GAs (other GA branches).

As in the business sector, GAs with successful models of structure and operations undergo a kind of organizational evolution and dispersion in their own societies of origin,

sometimes also spreading internationally. These successful models of monomorphic GAs thus sometimes are transformed into polymorphic, supralocal associations over time, either combining with similar GAs or establishing a new, supralocal association. In the course of decades or longer, however, even successful polymorphic associations or *types* of polymorphic associations may die out as the needs of people and the circumstances in their society change. For instance, occupational guilds have died out and been replaced by trade unions, representing the workers, not both workers and owners. Putnam (2000) has documented the decline of traditional, polymorphic, membership type of associations in the United States in the last third of the twentieth century. Similarly, Skocpol (2004) has shown a trend toward the more professional, paid-staff-management type of associations in the United States, and the decline of earlier member-based leadership of associations.

Isolated versus Collaborative Associations

Being a polymorphic branch GA of a supralocal association is a *vertical* kind of collaboration with another association. There is also *horizontal* collaboration of a GA with other associations in its own community or locality. Some GAs cooperate with other local GAs on short-term projects of common interest. But some GAs also join long-term networks, federations, or councils of GAs with similar or overlapping goals. For instance, environmental GAs or women's rights and services GAs often join together into such cooperative ventures in a given city or metropolitan area.

As with vertical collaboration in polymorphic GAs, horizontal collaboration by GAs in networks strengthens the GAs involved in various ways: Member GAs gain access to new resources (money and members), achieve broader collective impact in their service or issue area, gain greater public name recognition and prestige, and are more likely to survive longer than isolated GAs. Inter-GA collaboration can lead to fruitful mergers, with the new association being stronger by synergy and its larger size and resources. Many regional, state/provincial, national, and international associations have formed as a result of such fruitful mergers. In unity there is strength, both locally and supralocally. Many association leaders act on this knowledge.

Liveliness and Intensity of Activity

Associations are living, collective entities – one might even say, 'social beings' or 'social organisms.' As such, they have a definite life cycle and an average life span. GAs tend to have a short life span (5–10+ years), whereas national and international associations tend to have a much longer life span (20–30+ years). Knowing that a given association is clearly active and 'alive' is a crucial analytical factor, of *far* greater importance than its purposive type and goals. Many associations gradually fade away and die (disappear, exit, dissolve), or they become comatose and moribund (inactive, but still alive), without many outsiders or nonmembers realizing this. The names of associations may remain on local, state or provincial, national, or even international lists or registries for years, after all group activity has ceased.

For instance, the U.S. Internal Revenue Service (IRS) recently flushed about 400 000 registered charities from its national list of tax-exempt organizations, including many associations. This event resulted from VO inactivity and failure to file annual reports with the IRS. Unlike plants or animals, groups like associations are more difficult to declare 'dead' (defunct; permanently inactive). Associations have no physical bodies and exist mainly in people's minds and in their overt activity patterns. The belief in or desire for an association can persist long after regular, overt activity has ceased, making a declaration of death tricky. Comatose associations can spring back to lively activity if a new and energetic leader gets involved or significant new resources are obtained. This situation is very different than for businesses or even government agencies, where bankruptcy and loss of government funding are clear indicators of death.

The Nature and Degree of Personal Contact

Human groups must involve some degree of interpersonal contact or linkage, by definition (Smith et al., 2006: definition of 'group'). True groups are not mere analytical categories of people, such as women or farmers, as common usage sometimes suggests. How personal contact occurs and how often it occurs are important aspects of associations that also vary markedly. In preliterate societies and thereafter, GAs have long involved regular meetings in person, from daily to weekly. Strong and enduring personal relationships usually were involved, at least with some other members, and often with all or nearly all other members. For most of their existence, GAs have been 'primary groups,' to use a technical term, developing deep friendship relationships often rivaling family ties.

As human societies increased in size and complexity, however, GAs, and especially supralocal associations, usually became 'secondary groups,' with weaker interpersonal ties and fewer such ties in any given association. Personal contact with other members became less frequent as well as less intense or deep in quality. Supralocal associations, with larger geographic scope, have arisen especially in the past two centuries, along with various mass and personal communication media that have permitted mediated personal contact (by mail, telegraph, telephones, cell phones, the Internet, satellites). Supralocal associations usually meet only once (or a few times) a year, in conferences or similar large meetings. Few members know many other members, let alone have deep and personal relationships with them (virtually never with all members).

A new and more recent phenomenon is 'tertiary associations,' as associations in which there are few personal relations or contacts at all with other members, on average. In large, national or international associations, members often merely are people who have paid their annual dues or made a contribution in the past year. For instance, members of the nearly 40-million-member AARP in the United States rarely if ever see or talk with any other members in meetings or conferences. They are listed as members and enjoy membership benefits, such as discounts on certain services or products, but they never see or contact each other personally. This is very different

qualitatively from the deep and primary relationships of GAs in earlier centuries and millennia. In GAs when they were (or are) primary groups, members met (meet) daily or weekly and enjoyed personal contact with deeply meaningful and enduring social relationships.

Clearly, the dynamics of leadership, recruitment, internal structure, activities (if any), member benefits, power, funding, and the like are very different in primary, secondary, and tertiary associations. Perhaps most striking is the huge decline in social or solidarity benefits for members, as one goes from primary to secondary to tertiary associations, historically or analytically. Put another way, only GAs as primary associations retain all of the original social and relationship benefits of associations. Even these 'expressive' benefits have declined in most contemporary GAs, relative to centuries or millennia ago. Secondary and especially tertiary associations have mainly instrumental benefits (achieving some specific goal other than enjoying social relationships per se), with fewer social, solidarity, or personal relationship benefits, if any at all.

Restrictiveness of Membership Criteria

One of the most pervasive and central benefits of associations is their exclusivity. Associations significantly restrict personal relationships, focusing these mainly on other members, at least during group meetings and events, but often outside them as well. This exclusivity often conveys both prestige in the eyes of outsiders (nonmembers) and higher self-esteem in the eyes of members. Humans everywhere value prestige and enjoy self-esteem. As a result, determining the requirements for being accepted as a member of an association is important.

For the earliest associations, as GAs in preliterate horticultural societies, the requirements were simple: be male and of sufficient age (an adult, however defined locally). For most of the history of associations, GAs have been social clubs (Smith, 1997). As time passed and societies grew in size, membership requirements often became more restrictive. In general, associations have higher prestige when they have more restrictive membership requirements or when they mainly have wealthier and more powerful members. More recent social clubs usually have required sponsorship by an existing member of the club (Ross, 1976). Really exclusive social clubs or other exclusive associations often require that each new member be acceptable to all existing members. If a single existing member rejects a new member-candidate (i.e., 'blackballs' the person), the candidate cannot join. This practice emphasizes the highly social nature of such clubs.

Early religious GAs two or more millennia ago in Greece or Rome required new members to believe in a particular god or goddess, or a religious patron or ancestor (Kloppenborg and Wilson, 1996), and in the case of Christian GAs, to believe in Jesus Christ and His resurrection. Early guilds in ancient Rome required that members be involved in a certain trade or occupation, such as metalworking (Ross, 1976). GAs have always had age requirements, excluding infants and young children, and often all nonadult younger people. Until the past century or two, GAs also tended to be exclusively male, although this has changed markedly with the rise of women's rights and the feminist movement worldwide (Smith, 1997; Skocpol, 2004).

A wide variety of purposive types of associations have arisen in the past two centuries, especially in the twentieth century. Many of these have had restrictive membership requirements, but others have been open and inclusive. Large national associations seeking to maximize membership size and donors or dues-payers have been especially inclusive (e.g., the Parent–Teachers Association or the Sierra Club in the United States), often as secondary or tertiary associations. Recent research shows that in any given community in an industrial nation, GAs tend to reflect most or all of the 'demographic niches' for males and females, young and old, rich and poor, educated and less educated, and even major racial-ethnic categories. If a new GA arises in a niche already occupied, it likely will have difficulty surviving for long, given existing local competition. This analytic approach is termed the 'population ecology of associations.'

The Prestige and Power of Associations

In general, GAs have relatively little power or prestige compared with the power and prestige of government agencies and large business firms, let alone compared with old and wealthy families (e.g., the Rockefellers or the Mellons in the United States or the 'nobility' in European nations). But some associations have great prestige, nonetheless. All associations in a community or nation can be placed somewhere on a continuum of combined prestige, power, and wealth – calling the continuum 'dominance.' In U.S. towns and cities, the dominant GAs tend to be civic service associations like Rotary, Kiwanis, and Lions, with mainly high prestige male members, but no longer with males exclusively. Business and Professional Women's Clubs also have high prestige. In the United States, the Junior League has long been a high-prestige women's social service association in communities nationwide.

There are also exclusive social clubs for wealthy and powerful persons residing in urban areas of industrial nations, including so-called country clubs (for golf or tennis) or sporting clubs (for horse racing, cricket, or polo) and other, urban, elite, social and dining clubs. Nationally, very high prestige often is associated with elite professional, academic, or honorary associations. Alumni associations of high-prestige universities tend to have high prestige, as do national academies in the sciences and in the arts and humanities (e.g., the National Academy of Sciences and the American Academy of Arts and Sciences, in the United States). In many high-prestige occupations and professions, there are special academies as professional associations, which honor people with specific outstanding achievements or remarkable careers.

In all of these instances, association prestige as a value tends to follow economic scarcity principles. Associations with the highest prestige are generally the most exclusive in terms of small size and costly membership requirements (including academic degrees). The fewer the available memberships (scarcity), the higher their value is to those seeking to enter or already members. When such memberships also convey material and social benefits, high prestige usually is ensured. Not surprisingly, all high-prestige associations are conventional or mainstream associations, not DVAs.

Nature and Degree of Impact

The dominance continuum for associations referred to deals with public *perceptions* of the value and importance of an association – basically, its reputation. In this section, we consider the *actual impact* of an association on its members, on other associations, and on the larger community or society. Perceived reputation or dominance usually is correlated positively with actual impact, but the relationship is not perfect. This is especially true regarding the impact of an association on its members. Associations with low dominance ratings, including DVAs, may have substantial impacts on their members as active volunteers.

The proliferation and persistence of many kinds of associations in nontotalitarian societies worldwide is one indicator of their actual impact. If association members did not receive significant benefits from their membership(s), associations would not survive, either individually, as specific-purpose types of associations (e.g., self-help groups, labor unions), or as a general form of human group. Recent research (e.g., Smith, 2000: Chapter 9; Smith et al., 2014: Chapter 57) shows clearly that member volunteering in associations leads usually to many positive outcomes for participants. Such positive impacts include better mental and physical health, greater happiness and satisfaction, better social relationships and more social capital, political empowerment and influence in many cases, greater information and certain skills, and sometimes economic and occupational advancement.

Looking at the larger community, many associations have clear and positive impacts on local problems and issues. For instance, the national association in Bangladesh with the acronym BRAC has been extremely successful in helping poor people there and elsewhere in the Global South with their own economic development and poverty issues (Smillie, 2009). This is not an isolated instance, as Fisher (1993) has shown convincingly. Local-development GAs and supralocal, grassroots, support organizations are two keys to sustainable development in developing nations, she has argued. Even when considering related issues in the Global South, associations have important roles to play, such as in helping urban migrants adjust in big cities (e.g., Little, 1965). GAs also may have negative impacts on their members or on their local communities. Delinquent juvenile gangs are one of many possible examples.

At the level of nations, associations have had a major impact throughout the industrial nations and often in Eastern and often in Global South nations as well, both positive and negative. As a beginning, political parties are associations, and have had vast importance and impacts in the politics of most modern nations, including one-party states. Some parties have brought freedoms, but others have brought oppressive dictatorships. Delving deeper, social movements and especially their component social movement organizations are associations that have changed history worldwide in the past two centuries. Social movement associations have significantly helped the situations of slaves, farmers, laborers in factories, women, children, older people, racial-ethnic minorities, the disabled, gays and lesbians, and many other categories of historically disadvantaged people with special needs or problems (Gamson, 1990). Associations have been vital components and preservers of democracy in many nations (Warren, 2001), as manifestations of the participatory essence of civil society. Voluntary *agencies* rarely play this vital role in civil society worldwide, lacking most participatory elements present in associations.

At the global level, it can be argued that INGOs, as international associations, have been global moderating influences, often ameliorating or resolving transnational conflicts, as well as building world culture, for the past century and more (Boli and Thomas, 1999). Even the many intergovernmental organizations (IGOs) of the world, like the United Nations and the Organization of African Unity, are in fact associations of governments as organizational members. These IGOs play key roles in peace and war, providing multinational forums for discussion and delivering certain key services as public goods, including fostering economic and social development. But there are also noxious and harmful INGOs like Al Qaeda that are active on an international scale. Like all other types of human groups (families, businesses, governments), associations mainly do good and useful things, but also can do harmful things at any geographic level (Smith and Eng, 2013).

Conclusion

Associations exist in a bewildering variety of forms, structures, sizes, and geographic scopes. On the basis of the current global population and the estimated global prevalence of seven associations per 1000 population, approximately 56 million associations worldwide exist at present. Of these, about 50 million (roughly 90%) are GAs. An estimated 1 billion people now are members of one or more associations, and even more will be members sometime during their lifetimes. The cumulative monetary value of time contributed by active association members as volunteers was at least US$500 billion in 2005, according to one research-based estimate (Smith et al., 2014: Chapter 44). Associations also have cumulative global incomes and assets in the hundreds of billions of U.S. dollars. Many associations strongly support the economic systems and economic development in their own nations and globally.

There are associations focused on every topical area, idea, belief, issue, and problem in contemporary nations having nontotalitarian political regimes. Beginning mainly 10 000 years ago as social clubs, associations now tackle every type of problem and potential benefit for members or for the larger society, often having significant impacts. Sometimes these impacts are unintentionally negative or harmful to members or nonmembers or both; associations also can be intentionally harmful. The members of associations mainly participate during their leisure time. But such associations can and often do serve economic and occupational needs and goals, as well as conventional political, social movement (activist), religious, health, education, social welfare, self-help, economic development, and indulgent leisure needs and goals.

Most associations in any nation are conventional and law-abiding, but some break the law on a long-term basis, as DVAs. Social movement associations in particular, although initially seen as DVAs, often turn out to be the *positive* 'dark energy' of the voluntary nonprofit sector. Such associations frequently

foster positive social innovation and sociocultural change in their own nations and sometimes in the world as a whole. Governments and businesses mainly *run and control* the world, but certain associations *permanently change* the world, including changing government regime structures and entire national business and economic systems.

Voluntary, nonprofit, membership associations are a persisting and persistent third force to be reckoned with in the world and in every contemporary nation. This is even true in totalitarian dictatorships, where some independent associations usually exist underground in secrecy. Associations as a whole cannot sensibly be ignored as irrelevant, weak, or unimportant. However small specific associations may be, many are in existence at a given time in a given nation, and however much their existence and activities apparently are controlled or suppressed by the government. Associations are a key form of human group that has unlimited potential, as history has demonstrated.

Voluntary Organizations

Abstract

Voluntary organizations have two main subtypes: voluntary agencies (VolAgs) and voluntary associations. This article deals with VolAgs, usually nonprofit service organizations with a paid staff, while a different article deals with voluntary associations. The article reviews VolAg history, incidence and prevalence, formation and life cycles, scope and types, goals and missions, governance and management, government relations, resource attraction, impact and outcomes, and research and usable knowledge.

According to Merriam-Webster's Unabridged Dictionary, the word 'voluntary' means an action of will or choice. Voluntary organizations (VOs) fit with this definition by being organizations that people join and participate in by their own free choice, not because of compulsion by law or force. By common definitions, VOs are also distinctive in having not-for-profit (nonprofit) primary goals, as contrasted with business organizations (businesses), which have for-profit primary goals. There are various other common names for VOs, the most frequent being 'nonprofit organizations' (NPOs), 'nonprofits,' 'nongovernmental organizations' (NGOs), or 'civil society organizations' (CSOs).

There are two main structural types of VOs: associations and nonassociational nonprofits (Smith, 2000: p. 30). Associations, usually called voluntary associations (or sometimes membership associations), are treated in a different article in this encyclopedia, under the heading 'Voluntary Associations, Sociological Aspects.' The present article discusses nonassociational nonprofits as a subtype of VOs. The simplest label for this subtype of VOs is 'voluntary agencies' (VolAgs). VolAgs usually have significant respect and prestige in their societies, and are perceived as useful and altruistic.

Many people confuse voluntary associations and VolAgs, or incorrectly use the term 'voluntary organizations' to refer just to one type or the other, not to both, which is correct. Others similarly fail to understand how different the two basic VO types are in their basic structure. Simply put, voluntary associations have a structure in which there are members who hold the ultimate power, while VolAgs usually have a board of directors (or trustees) that holds the ultimate power. VolAgs (sometimes called social agencies or welfare agencies) have no members, but have paid staff and often volunteers.

In a voluntary association, members elect the top leaders (board members, officers, sometimes key executives) on a regular basis (e.g., annually, biennially). In a VolAg, the Board of Directors (Trustees) is self-perpetuating, electing or appointing new members as needed, sometimes annually or biennially. There is no category of members as a kind of affiliate, just employees and volunteers. In sum, voluntary associations practice a kind of internal democracy, while VolAgs usually do not practice internal democracy. VolAgs are generally structured more like government agencies or business corporations, as hierarchical bureaucracies with the power at the top. This crucial difference in basic internal structure makes these two subtypes of VOs very different in their operations, organizational culture, resource attraction processes, and impact on participants, among other effects (Smith, 2000: p. 30). Smith has argued that these two VO subtypes constitute different subsectors of the voluntary nonprofit sector (VNPS), third sector, or civil society sector.

The History of Voluntary Agencies

The earliest VOs were voluntary associations, originating perhaps 25 000 years ago (Smith, 1997). Such associations became common about 10 000 years ago when human societies settled down in agricultural villages after 100 000–200 000 years as nomadic bands of less than a 100 people each. These horticultural villages had an average of 1500 people, so that subgroups now made sense.

Many thousands of years later, in the ancient empires of Egypt, Greece, and Rome, some VolAgs arose, although their independence from the government was questionable in most cases. A reasonably clear example of an ancient VolAg was Plato's Academy in Athens, as an early protocollege (*c.* 387 BC and thereafter), and subsequently Aristotle's Lyceum (founded *c.* 335 BC). There were also ancient universities founded in Asia and the Middle East.

There was an Ancient (or Royal) Library at Alexandria in Egypt from the second century BC until destroyed by fire in 48 BC. Although supported financially by the government of the Pharaohs, the library had some independent VolAg features. Probably the first VolAg hospital was at the Temple of Aesclepius at Epidaurus in Greece (from *c.* 430 BC). Later, a similar Aesclepium was built in Rome (second century BC). VolAg hospitals in Rome were built during the Christian period of the Roman Empire, after Constantine legalized the religion (AD 313 and thereafter). For instance, St Basil founded a Christian hospital in Cappadocia, Turkey (*c.* AD 370), and many others were founded throughout Europe and the Middle East in later centuries of the Middle Ages. Particularly distinctive were Arab hospitals early in the second millennium, which admitted all sick or injured people regardless of religion, race, etc.

Early monasteries, unlike churches, were VolAgs. Buddhist monasteries (termed 'vihara') seem to have arisen first, in the third century BC in India and Bangladesh. Some of these later became early Buddhist universities. Vihara spread to many other Asian nations in later centuries. St Pachomius founded

the earliest Christian monastery in Egypt (*c.* AD 318), with hundreds more being founded there and in Middle Eastern nations subsequently. St Benedict founded the first Western monastery at Monte Casino in Italy (*c.* AD 529), which became a model for hundreds of others in Europe subsequently. Shankara founded Hindu monasteries (termed 'mathas') in India beginning in AD eighth century. Other Hindu sects later also formed mathas in India.

Independent (nongovernmental) elementary and secondary schools as VolAgs (but part of the Catholic Church) were formed in medieval England. First was The King's School, Canterbury (founded in 597), then St Peter's School, York (founded *c.* 627), followed by many others in the 600s and thereafter. The first VolAg secondary schools independent of the church in the United Kingdom were Winchester College (founded in 1382) and Oswestry School (founded in 1407).

Some types of VolAgs as we now view them have arisen mainly in the past millennium. Classic examples are the University of Bologna (founded in 1088), Oxford University (founded in 1096), the University of Paris (founded in 1150), the University of Modena (founded in 1175), and Cambridge University (founded in 1209).

The earliest museums, as collections of artifacts of interest, were private and personal, owned by wealthy collectors. The Ennigaldi-Nanna's museum dates to *c.* 530 BC, founded and led by a Babylonian Princess in Ur (modern day Iraq). Museums open to the public arose in the Renaissance, with the Capitoline Museums of Rome being the first (founded in 1471). The Vatican Museums in Rome came next in 1506. As part of the Roman Catholic Church, this museum was more clearly a VolAg, unlike most subsequent major museums, which were national or municipal government agencies. Many other public museums followed, especially from the 1700s on, some of them being VolAgs.

Almshouses are one of the earliest forms of VolAg social welfare agencies, dedicated to providing lodging, and often food, to the poor, especially the elderly and single poor. The oldest surviving almshouse in the United Kingdom is called the Hospital of St Cross, founded *c.* 1133 in Winchester. Many others were formed subsequently as VolAgs in the United Kingdom and in other European nations (e.g., the Netherlands). Almshouses in the Middle Ages were often called 'hospitals,' giving hospitality/care to the old, poor, and feeble, as well as to people with specific mental or physical health problems. Poorhouses or workhouses were not VolAgs, but were government-run places for the lodging of the poor and elderly, requiring labor from their residents.

Orphanages for children without living or functional parents arose as Christian welfare VolAgs in the first century AD and have existed down to the present as a VO subtype in many nations. In the Middle Ages in Europe, monasteries often acted as VolAg orphanages. Germany and the Netherlands had VolAg orphanages from the late 1500s. The first VolAg orphanage in the United States was founded in New Orleans by the female religious order of Ursulines (1727). Orphanages as VolAgs spread to many nations in Asia, Africa, and Latin America via religious missionaries from about 1600.

There are many other kinds of social welfare VolAgs now in existence, focused on specific disabilities (blindness, deafness, developmental disabilities, low intelligence, physical limitations of the body, etc.), homeless shelters, shelters for battered/abused women or children, immigrant and refugee centers/shelters, earthquake and flood victim shelters, alcohol and drug addict halfway houses, exconvict halfway houses, vocational rehabilitation centers, day care centers for children, etc. The vast majority of current VolAgs have been founded in the past century or so. Although many have religious underpinnings, there are now many others that are secular.

Factors Affecting the Incidence and Prevalence Rates of VolAgs

From the above, it should be clear that the general economic development level of a society has a major effect on VolAg formation (e.g., incidence rate in a territory or society) and existence/growth/decline/demise (e.g., prevalence rate). In preliterate, nomadic, hunting–gathering societies, there were no VOs, including both subtypes. In preliterate horticultural (village) societies, the somewhat higher economic development level permitted somewhat larger populations, owing to primitive agriculture (called horticulture – basically just gardening). However, the VOs formed there were voluntary associations, never VolAgs (Smith, 1997).

When there was more advanced agriculture (with plows, fertilizer, irrigation, etc.), as in major ancient civilizations, much larger populations could be supported in urban places (towns, cities, metropolises, and megalopolises). However, VolAgs were quite rare until the Industrial Revolution, which caused an Organizational Revolution (Boulding, 1953). This higher level of economic development and efficiency provided an economic surplus that some wealthier people used to form VolAgs that they believed would serve segments of the population not served by families, governments, or businesses. In addition, government permissiveness of VolAgs was necessary for their formation and operation in a public (vs. underground) manner. Greater communication–transportation network development and the rise of mass education accompanying the Industrial Revolution also facilitated VolAgs, as did greater population size in a place or society.

Accompanying these larger population densities in ancient civilizations from about 500 BC was the growth of government and business organizations and bureaucracies, with greatly increased differentiation of occupations inside them and independently of these bureaucracies. This greater division of labor led to different economic interests of people in different occupations, which facilitated the formation of occupational voluntary associations (e.g., in ancient Rome; Smith, 1997) and also certain VolAg types.

The Formation and Life Cycles of VolAgs

When one or more founders (we will consider the term 'founder' as potentially multiple henceforth) are considering the formation of a new service organization, such a group can potentially be located in any of three sectors of society: the government, business, or nonprofit sector. Founders usually choose the voluntary nonprofit sector (VNPS) when forming a service organization, since a government agency is unlikely or too time

consuming to form, and since earning a profit is not a paramount goal.

Once the VNPS has been chosen as a societal location, the next founder decision is whether the new group is to be a VolAg or a voluntary association. VolAgs are usually chosen as the appropriate VO form when the new group is to have mainly a social service goal and when paid staff are anticipated to operate the group. The founder also must consider in which nation and city/town/area to have the physical base of the group.

Additional founder decisions that are usually made by VolAg founders (Smith, 2000: Chapter 3) are (1) to have a nonmember-benefit or 'public service' goal, (2) to be conventional or mainstream, rather than deviant or underground, relative to national and local laws, (3) to have some or all paid staff to run the VolAg rather than only volunteers, (4) to have a nondemocratic, corporate-like structure with top-down control by the initial leaders/board, (5) to specify the territorial scope or catchment area of people to be served, (6) to specify what types of recipients are to be served (e.g., the general public, children, the aged, veterans, poor people, or sick or handicapped people), and (7) to specify what services are mainly to be provided (e.g., education, health, exercise, preservation of artifacts or art, funds, food, or lodging).

More variability is found with regard to founder decisions about the specific ideology of the VolAg, the degree of dependence on volunteers (as in a VolAg volunteer program), how to attract and keep volunteers, sources of funding, how to recruit and keep suitable paid staff, linkages or subordination to existing organizations in any sector, whether and where to incorporate as a legal person, whether and where to register formally with the government, whether to seek formal tax exemption from the national government, where and how to have a physical base/office for the group, and the degree of formality vs. informality of internal structure and operation.

VolAgs tend to live longer on average than voluntary associations, because more effort goes into forming and running them, they tend to have more assets and income, and their paid staff want to keep their jobs. VolAgs are also better able to resist economic downturns than businesses because of the leader commitment to their missions (Bowen et al., 1994: p. 99). As with any kind of organization, there is a 'liability of newness' for VolAgs (Bowen et al., 1994: p. 104). Younger VolAgs are more likely to fail/die than older ones. There is a kind of Newtonian momentum to organizations once well established. Wealthier VolAgs are also less likely to fail/die. VolAgs very rarely transition into being businesses, or vice versa, but may become social enterprises as voluntary–business sector hybrids. VolAgs very rarely transition into voluntary associations, or vice versa.

Block (2004) has discussed several major reasons why VolAgs fail: (1) failure to do adequate orientation of board members; (2) a negative or depressed organizational culture/atmosphere; (3) leaders acquiring and using power to benefit themselves, not the VolAg mission; (4) confusion regarding roles/duties of board members, executive staff, and committee members; (5) financial misfortune and loss of funding/income; (6) 'fund phobia,' or fear of asking people for financial contributions; and (7) domination or control of the organization by the founder over an extended time period.

Additional factors in demise can be substantial fraud or abuse by organization leaders or staff, or other significant violation of laws and regulations. VolAgs are as susceptible to crimes and misconduct as are businesses and government agencies (Smith and Eng, 2013; Zack, 2003). Deviance is a human quality, not confined to any one sector of society or type of organizations.

VolAgs need to engage in risk management by purchasing insurance against various kinds of misconduct and implementing internal controls and external audits (Renz et al., 2010: Chapters 22, 23). There are also various kinds of social accountability and social accounting that need to be performed (Renz et al., 2010: Chapter 4).

Scope, Magnitude, and Types of VolAgs

In all contemporary societies where they are present, VolAgs tend to be larger in assets and income on average than voluntary associations in their society. Voluntary associations usually include more participants than do VolAgs, most participants being members and many being active members or associational volunteers. VolAgs usually have more paid staff in the aggregate, compared to associations in a nation. VolAgs are much more likely to own or rent their own office space continuously, compared to voluntary associations, and are much more likely to have a listed telephone number in a directory and to have a Website for the organization. The generalizations above are more accurate for more economically developed societies in terms of average level of education and gross domestic product (GDP) per capita.

Research by Salamon et al. (2004: p. 17) showed that 56% of the full-time equivalents of the nonprofit sector work force are paid staff (vs. volunteers) for the 36 nations studied, comprising 4.4% of the economically active population (p. 16). Most of these paid staff were probably employed in VolAgs, not in voluntary associations. The proportion of the paid work force in VolAgs was substantially higher in developed nations than in developing or transitional nations (pp. 18–19). Salamon et al. (2004: p. 16) also found that VolAgs' expenditures were 5.4% of the combined GDP of the 36 nations. VolAgs are thus a significant global economic force.

The vast majority of VolAgs in most nations fall into the categories of religious congregations and faith-based organizations, nonprofit secondary schools or colleges/universities, hospitals and other health agencies, museums, research centers, social enterprises, social welfare agencies, sports and recreation organizations (especially leagues and federations), art and cultural organizations, advocacy organizations, and foundations. In more developed nations, there are also transnational aid, relief, development, and friendship as well as environmental and advocacy VolAgs. O'Neill (2002) describes and discusses the major types of VOs for the United States, as do many other authors for other nations. Various classification schemes have been suggested as typologies of VolAgs (e.g., Bowen et al., 1994: p. 21; Salamon et al., 2004: p. 12; Smith, 2000: pp. 4–5).

Goals and Missions of VolAgs

Governments usually have as key goals control over the residents in their territories (e.g., maintaining the peace and conformity to laws), maintenance of the current leadership

power structure, generation of tax revenues, and the provision of some public goods (e.g., roads, bridges, water systems, sewer systems, defense, and wars). Businesses have as key goals the generation of a profit for the investors/owners based on income from the sale of private goods or services, longer term growth in company assets and income while protecting capital, greater market penetration, and maintenance of stability of the company labor force, including management.

By contrast, VolAgs may have a wide variety of goals unrelated to control/power and unrelated to assets/income/profits. VolAgs face issues related to such goals, but put primary emphasis on public service or nonmember benefit goals. VolAgs usually develop and change/expand their goals so as to meet some perceived needs of the people they intend to serve, based on an altruistic concern for such recipients of VolAg services. However, VolAgs may also change their goals subsequently to serve the needs of the managers and paid staff of the VO. This can be termed 'mission drift' or 'goal succession' to put it kindly, but 'mission abandonment' or 'organizational maintenance goal' to put it more bluntly and honestly.

When there is a financial surplus of income relative to expenses for a VolAg in a given year, the surplus is not divided among the owners, managers, or original donors of funds, contrary to the practice in most businesses. The surplus (technically, not a profit) is plowed back into the VolAg, but usually benefits the managers and staff, and to a lesser extent recipients of its services in the future. This practice is quite distinctive of VolAgs as contrasted with businesses. Hansmann (1980) terms this, famously, the 'nondistribution constraint.'

VolAgs very rarely produce physical goods, but mainly provide services to their recipients (customers, users), unlike manufacturing businesses. Economists call these services of VolAgs 'club goods.' As such, they stand in marked contrast to the 'private goods' (divisible and usable by individuals) provided for sale by businesses or the 'public goods' (indivisible and usable simultaneously by all or most people residing in a territory) provided to residents by government agencies. Club goods are goods (usually services as goods) that are provided to a limited set of individuals because of their special relationship to the provider organization, such as a particular VolAg. The term 'club goods' originated because economists were analyzing the special benefits (goods) provided by voluntary associations (clubs, broadly viewed) to their members. The club goods concept also applies to the specialized clientele of VolAgs (e.g., hospital patients, museum attendees, university students, and food bank recipients).

VolAgs usually operate mainly with paid staff to accomplish their goals, and have done so as a type of VO for over two millennia. However, beginning in the late 1800s and especially in the past 50 years or so, VolAgs have developed volunteer (service) programs to use unpaid workers to perform some of the personal service activities directed at their goals. Such volunteer programs are not VOs of any kind. Rather, they are departments of other larger organizations that recruit, manage, and utilize volunteers to serve the goals of the larger organization (Smith et al., 2006: p. 244). Importantly, volunteer programs can be departments of a government agency (e.g., volunteers in a national park or government hospital), a business (e.g., volunteers in a for-profit hospital), or in a VolAg (e.g., volunteers in a VolAg museum or social welfare agency like the Red Cross/Red Crescent agencies).

The management/administration of VolAgs is typically a paid staff activity, sometimes very well paid staff (e.g., CEOs of large VolAg hospitals or universities). Volunteer boards of directors are usually parts of the governance structure, but not of the management structures of VolAgs.

Larger and wealthier VolAgs give stipends (essentially part-time pay) to their board members, and often provide expenses for travel to board meetings. The participants in the volunteer program are very rarely, if ever, part of the management, let alone the governance, of the VolAg. Sometimes the Volunteer Program Administrator (who may be paid full-time or part-time, or be a pure volunteer) is a minor part of the VolAg management team. VolAgs very rarely have affiliates who are genuine members, because they are not associations in basic structure.

VolAgs often place their primary goals in the context of an ideology and see the accomplishment of their altruistic goals as a mission, which involves much more commitment than a mere goal. Missions can involve commitment by VolAg staff (paid and unpaid) to goal achievement that transcends economic benefits to the staff, unlike nearly all businesses and government agencies. Thus, VolAgs usually have crucial expressive elements of staff commitment that can override purely instrumental commitments (i.e., commitments based only on salary or other financial compensation).

These expressive, moral, and ideological commitments of VolAg staff members are distinctive to VOs more generally. VO commitments often are even stronger on average in voluntary associations, where generating volunteer commitment among members and leaders is crucial to organizational survival. So-called mission statements of VolAgs may or may not properly formulate such expressive or moral commitments. Many VolAg leaders/managers do not fully understand the importance of these commitments to their existence and growth, and may mistakenly copy blindly the form of mission statements of businesses.

Another distinctive feature of VolAg goals is their sometimes-vague nature. The goals of a business or government agency are usually clear-cut, but VolAg goals are often diffuse, multiple in nature, and hard to pin down. This makes evaluation of the effectiveness of VolAgs more difficult than for businesses, where there is profit/loss as a bottom line. In addition, quite a few VolAgs espouse altruistic goals/missions, but in fact serve the goal of maintaining and expanding the VolAg and payments/compensation to its top executives and other paid staff. This 'goal displacement' implicitly and often gradually replaces seeking of the purported goals of effective and efficient VolAg service to its intended recipients. This situation raises the key issue of 'operational goals' (*de facto*) as contrasted with 'official goals' (*de jure*). Many VolAgs are essentially small (sometimes large) businesses masquerading as VOs to reap the tax benefits involved, according to critics (e.g., Gaul and Borowski, 1993).

Governance, Management, and Administration of VolAgs

In developed nations, the Board of Directors or equivalent (Trustees, Executive Committee, etc.) usually governs VolAgs

by making major policy decisions. This often results from institutional isomorphism in the requirements for a group becoming a legal person or incorporated NPO in many nations. A minimum of three directors is common, although upper limits of size tend to be set around 20 by practicality considerations, not laws. In developing nations, only a President or Board Chair may be legally required, and governance can thus be autocratic.

Even with multiperson boards, VolAg governance can be rather undemocratic for two main reasons: first, VolAg boards are usually self-selecting. Thus, they tend toward oligarchy, with a small subset of members dominating decision making over long time periods. Second, such boards are rarely required (or try) to be representative of recipients, of other similar service providers, or of any other definable category of persons. Hence, VolAg boards are only rarely democratically structured or adequately representative of key constituencies/stake holders (Guo and Musso, 2007).

Nations vary in the degree of control of VolAgs by the national government. All nations have laws requiring government registration of VolAgs, and most require annual reports to the government on expenditures and activities. National governments often limit political activities of VolAgs, especially if they are to keep their tax exemptions. Many nations restrict which VolAgs can register, receive tax exemptions, be legal persons, and operate legally.

This indicates the important role of freedom of association and other civil liberties in the formation and operation of VolAgs. Governments vary also in how closely they regulate VolAgs, with much greater government control in authoritarian nations. VolAgs practice self-regulation to varying degrees.

In most nations there are at least some government-initiated, government-financed, and/or government-controlled VolAgs. There are various special terms for such VolAgs: QUANGOs are quasi-nongovernmental organizations (such as the RAND Corporation in the United States). GONGOs are government organized nongovernmental organizations, common in China (e.g. most national associations).

In authoritarian and one-party nations, the nongovernmental character of VolAgs is usually questionable and variable.

The top administrative leader of VolAgs is usually termed the 'Executive Director' or 'Director,' and is charged with carrying out the policy decisions of the Board. However, the Director has leeway to interpret those decisions, and to make micropolicy decisions regarding implementation practices and timing. The Director usually makes all major operational decisions, including hiring and firing of staff, compensation, roles and tasks, supervision, etc. In essence, the Director answers only to the Board.

When the Director has a close relationship to the Board and its members are strongly committed to the Director, VolAg Boards may fail in their fiduciary duties and let Directors do more or less as they please, to the detriment of the organization (Fishman, 2007).

The top management staff of VolAgs is appointed, not elected as in associations. Leaders are less likely to be charismatic, as contrasted with associations, since economic incentives (salary and fringe benefits) influence staff compliance. Supervision of lower staff is usually high, with only moderate emphasis on human relationships. Priority setting by management tends to be tight and planned, and marketing is carefully managed. Public images of VolAgs are very important, because they strongly affect resource attraction.

The internal structure of VolAgs usually involves formal incorporation with the government as a 'legal person,' formal registration with a government agency, and formal tax exemption with the government taxation agency. VolAgs are usually more bureaucratic in structure than voluntary associations, being more like businesses and government agencies. They are usually monomorphic in character, having only a single location, rather than polymorphic, having two or more branches in different locations (Smith et al., 2006: pp. 146, 178).

The internal processes of VolAgs usually involve continuous daytime operation, often 7 days a week, sometimes for 24 h a day, unlike associations. Paid staff of VolAgs are often quite professional, with higher degrees in their specialty and a strong sense of professionalism. VolAgs often have high prestige and public recognition, sometimes wielding significant power both locally and in their states/provinces, even in their nations. They usually recruit paid staff and volunteers formally, do formal training of staff, and are quite willing to fire staff for inadequate performance, like a business or government agency. VolAgs tend to be more willing to collaborate with other organizations than are associations, and often relate formally to government agencies. Mergers and federations/networks are common among VolAgs, seeking strength in unified and cooperative efforts. There is much published literature for VolAg practitioners on governance and management, both in books and handbooks (e.g., Renz et al., 2010: Parts 2–5).

Resource Attraction by VolAgs

VolAgs are partly similar to service businesses in their resource attraction. Like service businesses, they depend heavily on fees for services – museum entry fees, school and university tuition fees, hospital patient fees, etc. Data reported in 2008 primarily for US VolAgs (Renz et al., 2010: p. 483) indicated that fees accounted for 70% of revenues in all types of VolAgs, especially for health, education, and human services VolAgs. Unlike most fees for service businesses, VolAg fees are sometimes subsidized by government agencies (e.g., Medicare and Medicaid payments to VolAg hospitals in the United States; Renz et al., 2010: p. 483).

VolAgs are especially distinctive from service businesses in receiving donations/gifts from private donors, both living donors and bequests at death as well as foundation grants, accounting for about 12% of revenues in the US data reported in 2008 (Renz et al., 2010: p. 483). Such gifts were most frequent in the US data for international, environment, and arts organizations (ibid.). There is a wealth of practical knowledge about how best to do VolAg fund-raising and other resource attraction (e.g., Renz et al., 2010: Chapters 18, 19). Large and well-respected VolAgs may have very large endowments, which are pools of investments/financial assets that are the long-term residue of gifts. The Bill and Melinda Gates Foundation, for instance, had assets of $37 billion at year-end 2011, while Harvard University had assets of $27 billion as of 30 June 2011. Investment income from endowments accounted for about 5% of VolAg income in US data for 2008 (ibid.).

Unlike associations, VolAgs often obtain external grants or contracts from government agencies, accounting for 9% of all monetary income for US VolAgs in 2008 data (Renz et al., 2010: p. 483). Government direct funding was most common for Human Services and International VolAgs. Government contracting for VolAg services is a growing trend worldwide (Renz et al., 2010: Chapter 21). Voluntary associations differ markedly from VolAgs in getting most of their revenues from dues (regular, usually annual payments to maintain membership) or donations, not from fees, grants, contracts, or investments except in very rare instances.

VolAgs also need to attract human resources in the form of board members, paid staff, and volunteers as unpaid staff. Although recruiting paid staff for VolAgs can be similar to recruiting similar staff for service businesses, recruiting volunteer board members and volunteer service staff is a special process that involves eliciting the altruism of potential workers.

A key problem of VolAgs is retaining volunteers, rather than simply attracting them in the first place. Many VolAgs have high volunteer turnover owing to inadequate volunteer management. Much is known about proper volunteer management to attract and retain volunteers (e.g., Connors, 2012; Renz et al., 2010: pp. 779–780).

Impact and Outcomes of VolAgs

The author has suggested (Smith, 2001) that VolAgs, as key parts of the VNPS, have a variety of major impacts on their societies, varying by nation according to their prevalence, size of paid and volunteer workforce, and freedom to operate. VolAgs help their societies by

- providing many kinds of partially tested social innovations;
- providing new and different definitions of reality and morality, often with advocacy activities;
- preserving traditional ideas, values, and artifacts for the future;
- providing education and training both for occupations and a good life;
- preserving and providing the sense of mystery, wonder, and the sacred;
- permitting individuals to reach the fullest expression of personal capacities and potentials in a limiting environment;
- providing a source of negative feedback and criticism to the dominant institutions of society, often with advocacy activities;
- providing support to the economic system of society;
- providing human services and financial resources to needy people, both domestic and foreign; and
- providing a latent resource that can be mobilized for any new and important goal that arises.

At lower analytical levels, there are four important types of impact of VolAgs: on recipients, on the staff, on the VolAg itself, and on the community. In broad terms, VolAg impact on intended recipients seems most important. Based on evaluation research of various kinds, there is evidence that VolAgs often have significant positive 'main effects.' Schools and universities raise the information levels of students, at least temporarily, and usually improve lifelong earning capacities. Hospitals have positive effects on patient health in the short and often long term. Museums often please and inform their attendees.

However, for some VolAg types, the outcomes are less clear. Evaluating the outcomes of monasteries or of orphanages and several other types of social welfare agencies is more difficult. Appropriate outcome measures for monasteries are hard to define in secular and empirical terms. As for orphanages, many experts now believe that empirical evidence shows orphanages do more harm than good, when compared to other ways of raising children without functional parents. International VolAgs have been particularly ineffective in facilitating economic development in places like Africa, and relief efforts in developing nations often just create more dependency (Smith and Eng, 2013). Foundations mainly tend to support status quo approaches to social and health problems, rather than supporting genuine social innovations.

Evaluation of VolAg impact on the paid staff has received little empirical attention. Research on VolAg volunteer program impacts on volunteer staff has been more extensive. Such volunteering has many positive effects, such as a greater sense of well-being, increased information, more felt social support, improved or maintained health, better subsequent jobs, etc. (Smith, 2000: pp. 196–205). However, there can also be negative impacts on volunteers, such as encountering contagious diseases more frequently, 'volunteer burnout,' and rejection of future volunteering owing to poor experiences with a given VolAg's volunteer management (or mismanagement) practices.

VolAgs themselves benefit from their own effective operations by facilitating the future existence and growth of the organization. Effective VolAg operation also facilitates maintained or increased pay and other compensation for paid staff. Effective operation also benefits volunteer staff, by continuing their volunteer service opportunities. VolAgs benefit their communities by taking some of the load off government-provided services for needy people, thus reducing the tax burden in the long term. Specific VolAgs benefit other local VolAgs by providing a supportive organizational field and often federations or networking opportunities. Certain infrastructure VolAgs specialize in supporting and helping other VolAgs, such as the Foundation Center or Independent Sector in the United States.

Some experts have argued that VolAgs play a significant role in promoting democracy and pluralism. However, this is not supported by empirical evidence. Voluntary associations do clearly contribute not only to democracy and pluralism in their societies but also to corporatism in some societies.

Research on VolAgs and Usable Knowledge

Although research on VolAgs goes back more than two millennia in terms of histories, social science research by sociologists, anthropologists, political scientists, and economists is historically very recent, beginning mainly in the twentieth century. The organized field of voluntary and nonprofit sector research began with the founding in 1971 of ARNOVA (www.armova.org), the Association for Research on Nonprofit Organizations and Voluntary Action. The new

International Council of Voluntarism, Civil Society, and Social Economy Researcher Associations (ICSERA; www.icsera.org) works to draw together all 30+ world region and national voluntaristics/altruistics researcher associations now existing worldwide and to provide global information on various aspects of research (e.g., academic journals, research centers). An overview of the development of VO and VNPS research is presented in Chapter 1 of Smith et al. (2014; see also Smith 2013, Smith and Associates 2015).

There are thousands of books and articles reporting research on VolAgs, many of which are summarized in handbooks like those of Powell and Steinberg (2006), Renz and Associates (2010), Salamon (2012), and Smith and Associates (2015). Smith et al. (2006) have written a dictionary of over 1700 nonprofit terms and concepts, with about 1800 references to relevant research publications. There is also much accumulated usable knowledge directed to practitioners (e.g., Block, 2004; Connors, 2012; Renz and Associates, 2010; Zack, 2003).

Abstract

The psychology of volunteerism has been informed by theoretical, empirical, and practical exploration. This article examines basic and applied scientific research on the antecedents, experiences, and consequences stages of the volunteer process. These stages of volunteerism are considered for individual volunteers, the recipients of volunteer services, the organizations through which volunteers serve, and the wider community in which volunteerism takes place. Theoretical and practical implications of volunteerism are also discussed.

Introduction

Each year, millions of people around the world provide voluntary assistance to individuals, groups, and causes by engaging in such behaviors as tutoring youth, providing companionship to the lonely, raising money for political causes, or organizing neighborhood groups. As diverse as these activities may be, they can all be classified as exemplars of volunteerism – voluntary action that aims to supply services to address the unmet needs of individuals, organizations, and communities.

Although volunteering has much in common with other forms of prosocial behavior, social scientists have identified criteria that make volunteering a distinct domain of prosocial behavior. Specifically, volunteerism is a thoughtful and deliberative behavior requiring the active seeking of opportunities for action, distinct from phenomena (such as emergency helping) that often find individuals in situations where immediate action and assistance are required. Much helping, including emergency helping, is a one-time, short-term effort that has costs only in the present moment, whereas volunteering often lasts for long stretches of time and can incur personal costs (such as time, energy, and resources) that can and do recur and even accumulate over time. This providing of assistance over time is similar to the experiences of caregivers who aid the chronically sick or those with disabilities. However, differences also exist between volunteering and caregiving, as caregiving often includes a sense of obligation or the bonds of a relationship (e.g., familial and marital). Volunteering, on the other hand, is often aimed at aiding a person unrelated or previously unknown to the volunteer. In some circumstances, a volunteer may never even meet the recipients of aid. Volunteerism can also be separated from other activities often found in communities and service organizations. Although some forms of volunteerism may resemble services provided by nonprofit and educational entities, such as classroom support or companionship for adults with disabilities, volunteers are not paid or reimbursed for their time and effort. This is despite the fact that volunteers do commonly work through established nonprofit and educational organizations, which often recruit, train, and place volunteers into service positions. Community activists, who often are volunteers themselves, may have similar goals as volunteers but instead work outside of established organizations to impact society and create change. In sum, it is this unobligated, long-term providing of planful assistance through established organizations without payment that constitutes a behavior as volunteering (for further elaboration on the defining and characteristic features of volunteerism, see Snyder and Omoto, 2008).

In the United States, volunteering has long been, and continues to be, a common form of community support. From September 2010 to September 2011, over 64.3 million people in the United States volunteered at least one time through an organization, equivalent to 26.8% of the country's population (Corporation for National and Community Service, 2011). Those volunteers spent, on average, 51 h per year volunteering for a wide range of causes at the aggregate level, although individual volunteers tended to spend their efforts within just one or two organizations (89%). The most common places to volunteer were in religious (35%) and educational (26.7%) settings; the most common activities of volunteers were fundraising (26.5%), collecting and distributing food (23.5%), and general labor (20.3%). With volunteer service valued at US$21.36 per hour, volunteers provided nearly US$173 billion of services during that year for the 8.1 billion hours of service they provided. Volunteerism is also a common activity in many other regions of the world, and is promoted by numerous organizations including the United Nations through United Nations Volunteers and the celebration of International Volunteer Day (Snyder and Omoto, 2008).

The psychological science of volunteerism has been a productive avenue of scholarly inquiry, not only exploring how volunteerism relates to other prosocial behaviors, but also examining the components of volunteerism that make it a distinctive and important topic worthy of study. Research to-date has considered factors that correspond to the antecedents of volunteerism, the experiences of volunteerism, and the consequences of volunteerism. These three stages of volunteerism have also been explored in studies of the volunteers themselves, the individuals aided by volunteers, as well as the organizations and communities through which volunteerism takes place. Research on these topics has approached the understanding of volunteerism from a variety of perspectives, including demographics, personality, identity, motivations, life experiences, and social contexts. The Volunteer Process Model proposed by Omoto and Snyder (Omoto and Snyder, 1995; Snyder and Omoto, 2008) is one structure for organizing

 http://dx.doi.org/10.1016/B978-0-08-097086-8.22021-7

theory and research on volunteerism, particularly the separate factors that predict when people decide to volunteer and who gets involved in volunteering (antecedents), the variables important to volunteer satisfaction and continued involvement (experiences), and the impact volunteering has on the volunteers themselves, the recipients of volunteer services, and the larger community (consequences).

Antecedents of Volunteerism

A wide array of factors and explanations have been proposed to explain the when, where, why, and who of the initiation of volunteering. At a sociological level, three demographic variables are commonly cited as being tied to volunteering: age, education, and income (e.g., Snyder and Omoto, 2008). Those in middle age, from 35 to 54 years, are the most likely to volunteer, and people in their early twenties are the least likely to volunteer. College graduates are substantially more likely than those without college degrees to spend time volunteering. Income is also positively related to volunteering and, in conjunction with being employed, makes one more likely to volunteer. Other demographic variables that have been noted include gender (women are more likely to volunteer), marital status (married people more commonly volunteer), parental status (those with children are more involved), and race (whites tend to volunteer at the highest rates). Although these demographic differences in rates of volunteering have been found in the literature, it is important to note that they do not necessarily imply causal explanations for the differences.

Moving beyond demographics, numerous psychological approaches have been taken to the scientific study of volunteerism in attempts to discover the underlying foundations and causes of volunteerism. One such approach to understanding why people volunteer is the functional approach (e.g., Snyder and Omoto, 2008). 'Why' questions in psychology are fundamentally questions about motivation, and the functional approach provides answers to the question of why people choose to volunteer. Motivational approaches to human behavior are focused on the reasons people act, why they choose a specific course of action over others, and why they sustain a given behavior. The functional approach focuses on the needs that are being met by an action, the motivations that are addressed, and the functions served by engaging in volunteer behavior.

The functional approach to understanding why people volunteer recognizes that different people may have quite different reasons for engaging in the very same behaviors. This perspective has provided insight into the distinct reasons why people volunteer. Among the motivations of volunteers are expressing personal values, the desire for understanding, to increase self-esteem, to strengthen social ties, to build community, and as a way to improve career possibilities. Research has also discovered that by matching recruitment appeals to the motivations of individuals looking to volunteer, recruiters may effectively boost interest in and intent to volunteer (for a review of research on the motivations for volunteering, see Snyder and Omoto, 2008).

Personality has also been implicated in the initiation of volunteer behavior; specifically, those who are more prosocial in disposition are more likely to seek out and engage in helping behaviors in general, and volunteering in particular (e.g., Penner, 2002). Prosocial personality has often been split into two components: other-oriented empathy and general helpfulness. These two aspects of prosocial personality are not always highly correlated, and relate to different aspects of volunteering. For example, other-oriented empathy has been linked to the number of activities that a volunteer engages in within the context of a particular organization, as well as the amount of time dedicated to that organization and overall satisfaction with the volunteer position; by contrast, general helpfulness has been linked to the overall number of organizations that a volunteer assists.

The role of empathy has also been considered in volunteer contexts that involve members of different social groups. Volunteers often engage in activities that directly aim to benefit members of various groups of people (such as the poor, individuals with disabilities, and people living with human immunodeficiency virus infection/acquired immunodeficiency syndrome (HIV/AIDS)). Sometimes, volunteers intend to assist individuals who are part of the same social group (in-group members), such as when a person who grew up poor volunteers to teach children currently living in poverty. At other times, volunteers serve individuals who are not part of the same social group (out-group members), such as when a person without HIV/AIDS is a companion for an adult living with HIV/AIDS. Research has explored the predictors of volunteering to assist in-group versus out-group members (Stuermer et al., 2005). These findings demonstrate that people tend to volunteer to help in-group members out of empathy and feelings of perceived similarity, whereas volunteers tend to choose to aid out-group members because they having feelings of liking toward the out-group members. Although empathy has been linked to volunteering overall, it may be a better predictor of volunteering to help in-group members as opposed to assisting out-group members.

Social expectations from members of our social networks have also been implicated as an antecedent of volunteering. Drawing on sociological concepts of roles, Grube and Piliavin (2000) posited that the roles that people are expected to fulfill influence their behavior, and this relation has been found to hold true for volunteerism. Specifically, when their friends and associates expect them to volunteer and otherwise get involved in their communities, people tend to seek out and engage in those activities that fulfill these expectations. On the other hand, if members of one's social network do not seem to value giving back to one's communities, it is less likely that people will become involved in volunteer service.

Outside of social expectations, the past experiences of volunteers have also been tied to volunteer behavior. Adolescents with family members who volunteer are more likely to volunteer themselves, as are those coming from families higher in socioeconomic status (Johnson et al., 1998). In addition, teenagers with higher grade point averages and who are more integrated into their communities are more likely to be volunteers. Research on volunteerism has found that, regardless of age, simply having people in one's social network involved in volunteering is a reliable predictor of volunteer initiation, as well as already being involved in one's community in other ways (Omoto and Snyder, 2010).

In addition to these life experiences, there are indications that exposure to crises and traumatic events can lead people to engage in various prosocial behaviors, including volunteerism (for a review, see Omoto et al., 2012). For example, in the aftermath of the terrorist attacks of 11 September 2001, in the United States, there was a spike in prosocial behavior (e.g., Penner et al., 2005). Similar trends have been found for the earthquake that struck Chile in 2010, where rates of donating and volunteering increased in the wake of it (Gabrielsen et al., 2012).

Even when not in times of crisis, factors at the community level have been linked to volunteer behavior initiation (Omoto and Snyder, 2010). Often, volunteer efforts are tailored to the conditions and contexts of neighborhoods and the needs of communities. In fact, many volunteer efforts actually attempt to make changes to the communities in which they are embedded. In this sense, volunteering can be thought of both as an outgrowth of community and as a social force important to the building and improving of communities. One component of communities that has been addressed in empirical research is residential mobility, that is, the extent to which people frequently move in and out of the community. This community-level variable has been tied to prosocial and volunteer behavior, such that those communities that are more stable tend to see more prosocial behavior among its community members (Oishi et al., 2007).

One particularly distinctive type of community that often encourages active involvement can be found online. Web sites that host and share user-generated content are now commonplace on the Internet, with examples of such Web sites being the online encyclopedia Wikipedia and the advice Web site Yahoo! Answers. These sites are places that contain an extraordinarily large amount of content that is developed and added by volunteers without any form of payment. This form of volunteering, often called 'microvolunteering,' has almost everything in common with traditional understandings of volunteerism but instead take place through online communities and organizations with an online presence. For example, recent research on the free movie review Web site MovieLens has explored the relation between typical predictors of volunteer behavior in order to understand the generation of volunteer user content on the MovieLens site (Fuglestad et al., 2012). Results indicate that there is a relation between other-oriented motivations (wanting to help others and the community) and various volunteer activities on the Web site, such as reviewing movies, editing movie information, and responding to questions on the forum board. Those with a history of community involvement and prosocial behavior in real life were also more likely to volunteer on the site. Finally, motivations specifically relating to joining the MovieLens site predicted different patterns of behavior such that utilitarian and personal entertainment reasons for joining related to rating movies but social motivations for joining related to more social volunteer behaviors such as interacting on the forum board.

Clearly, a wide range of factors play important roles in the initiation of volunteer behavior, including demographics, motivations, personality, identity, past experiences, and the community context. Many of these factors have also been implicated at subsequent stages of the volunteer process, as determinants of, for example, the satisfaction of volunteers and their sustained service over extended periods of time (e.g., Snyder and Omoto, 2008).

Experiences of Volunteers

As volunteers continue their service, new factors become relevant to understanding key facets of volunteerism such as volunteer satisfaction and continued volunteer behavior. Factors commonly considered in the literature include the matching of experiences to motivations, development of identity, and creation of community connections. Some of the earliest research on the experiences of volunteers comes from longitudinal studies of volunteer companions for individuals living with HIV/AIDS. Many of these volunteers had high expectations for the quality of the helping relationships between themselves and the individuals with HIV/AIDS, and yet many volunteers later felt that these relationships fell short of their own expectations (Omoto et al., 1998). This inability to have experiences that met their expectations left many volunteers feeling unsatisfied by their volunteer positions.

Research has also revealed that those volunteers who feel that they are gaining the experiences they desired when they started volunteering, and particularly those who feel there is a match between their motivations for volunteering and actual volunteer experiences, were most satisfied as volunteers and had stronger intentions to continue volunteering over time (see Snyder and Omoto, 2008). Some work has also demonstrated that, although people tend to start volunteering for other-oriented motivations, such as values motivations, self-oriented motivations have been found to more closely relate to overall length of volunteer service (Omoto and Snyder, 1995).

Volunteer satisfaction and behavior maintenance have also been tied to the extent to which people self-identify as a volunteer. The effects of identity have been considered in the Role Identity Model (Grube and Piliavin, 2000), which posits that role identity forms because of social expectations; that is, when people believe that others who are important to them want and expect them to engage in a certain behavior, they will develop a particular personal identity relevant to that behavior. This process has been found to hold true for volunteer role identity. Those high in volunteer identity consider volunteering a core component of their sense of self, and derive a portion of their self-esteem from involvement in volunteer service. The Role Identity Model has been linked to the experiences of volunteers over time, particularly how the forming of identity relates to satisfaction and future intentions. The extent to which volunteers form an identity as a volunteer and come to see the behavior of volunteering as important to who they are as a person, the more they are satisfied with their position, the greater the number of hours served, and the greater their intentions to continue to volunteer. Role identity has been linked to other, related prosocial behaviors such as blood and organ donation, but has proven particularly useful for understanding volunteer behavior and experiences.

The role of social expectations during required forms of volunteering, such as service learning in educational settings, also impacts individual volunteer behavior maintenance. Service learning programs that mandate volunteering as part of the curriculum are often designed to encourage positive contributions to a local community at the same time as they instill values of helping others into participants in service learning. However, research indicates that mandating volunteering does not always lead to future volunteering for students. For example, students in service learning classes who perceive the volunteering component of the class as having been under

their own control and intrinsically motivated are more likely to have their intentions to continue volunteering solidified by their service learning experiences than students who perceived their service learning volunteering as something imposed on by an external force (Stukas et al., 1999).

As reviewed by Omoto and Snyder (2010), although matching experiences to motivations and the forming of identity have been linked to volunteer satisfaction and volunteer behavior maintenance, a number of other factors have been linked to outcomes such as organizational support and organizational structure. It has been demonstrated that there are important factors related to the volunteer tasks themselves in regards to predicting volunteer behavior maintenance, such as task achievement of volunteers, the degree to which the volunteer tasks are challenging, and how involved the volunteer is in the organization and in the community. Finally, the existence and ongoing development of time conflicts between personal time and time spent volunteering has been recognized as an important contributor to volunteer behavior maintenance, such that having too many demands of time and energy decreases the likelihood that volunteers will stick with their current service position. Numerous organizational components and experiences have been linked to volunteer behavior maintenance.

Considering the community component of volunteer experiences, volunteers tend to form social and community ties over time as they get to know the recipients of help, other volunteers in the organization, and the staffs of the various organizations in which they serve (Omoto and Snyder, 2010). For example, volunteers who serve as companions for those living with HIV/AIDS tend to meet members of the social networks of the people they are helping, and in return the recipient of the volunteer's assistance also get to know members of the volunteer's community. In fact, the more that volunteers and the people they are helping become involved in each other's social networks, the happier and healthier the recipients of volunteer services tend to be.

However, Snyder and Omoto (2008) have also highlighted the ways in which experiences during the volunteer process are not always positive. Volunteering has been linked to negative impacts on individual's social networks and the individual's own life. It has been shown that sometimes volunteering with a stigmatized group, such as those living with HIV/AIDS, can lead to disruptions in the volunteer's social support. Members of the volunteer's social networks, including family and friends, might shun them or express disapproval of volunteer behavior aimed at supporting traditionally stigmatized groups. These volunteers have reported feeling uncomfortable and stigmatized themselves by their own social networks for helping individuals living with HIV/AIDS. These stigmatizing experiences predict early termination of volunteer service.

Factors that relate to motivations, expectations, identity, and community have all been linked to experiences of volunteerism, including satisfaction with volunteering and intentions to continue to volunteer over time. The question of how volunteering impacts volunteers themselves, the people they help, and the organizations and communities in which they volunteer is addressed in the consequences stage of the Volunteer Process Model.

Consequences of Volunteerism

Research on the consequences of volunteerism has considered its effects on the volunteers themselves, the recipients of volunteer services, and the wider community. Snyder and Omoto (2008) review outcomes that include changes in attitudes and knowledge, improved health and subjective well-being, changes in behavior, and the establishment of community bonds. For example, studies of volunteers who work with people living with HIV/AIDS have revealed that such volunteerism leads to increases in knowledge of safer sex practices, reductions in stereotypical beliefs about individuals with HIV/AIDS, and increases in comfort in discussing issues relevant to HIV/AIDS. Studies of consequences in other volunteer domains have found increases in volunteer self-esteem, self-efficacy and confidence, and even improved academic achievement. In addition, volunteering has been linked to positive health outcomes for volunteers, including increased optimism and longer life, and has been linked to higher subjective well-being for those volunteers who have experienced past traumatic life events.

As reviewed by Snyder and Omoto (2008), the benefits of volunteering extend to the actual recipients of volunteer service, and to the organizations through which volunteers serve. For example, individuals living with HIV/AIDS who have a volunteer providing companionship and home help have been shown to have better psychological functioning as compared to those without a volunteer companion. However, more research needs to be conducted on the impact of volunteer help on aid recipients, to determine, for example, whether receiving volunteer assistance might be threatening to recipients' self-esteem or self-efficacy. More research is also needed on the positive impacts of volunteerism on service organizations, to build upon the aforementioned economic benefits to organizations and the growth of social capital.

The building of community bonds and social networks occurs for volunteers, help recipients, and the member of the organizations through which volunteers serve (Omoto and Snyder, 2010). These community bonds have been linked to not only volunteer behavior maintenance, but also the willingness of community members to engage in other efforts aimed at improving the quality of life for the community, including the amount of money donated in support of causes, attending fund-raisers, and engaging in civic and political activism. In addition, these social networks increase the overall effectiveness of volunteers, as well as serve as means to recruit future volunteers.

Thus, psychological research on the consequences of volunteerism has documented benefits for individual volunteers, the recipients of volunteer services, the organizations through which volunteers serve, and the wider community. For volunteers and recipients, these include health and psychological benefits, as well as increased social capital. For organizations and communities, the benefits include improved capability to address problems and the ability to keep volunteers involved for longer periods of time.

Theoretical and Practical Implications

The lessons that have been learned from the psychological research on volunteerism can be used to assist organizations and communities in their efforts to create successful volunteer programs. Research can inform attempts to improve the recruitment, training, support, and retention of volunteers by guiding the development of recruitment materials, the framing

of volunteer positions, the creation of volunteer activities, and the types of feedback and experiences provided to volunteers. Furthermore, new possibilities for application could be gleaned from findings that relate to the role of matching motivations to messages and experiences, the forming of volunteer identity, building sense of community, and providing appropriate organizational support and volunteer opportunities, all of which could be incorporated into systematic efforts to improve the functioning of volunteer programs around the world. One possibility might be to have organizations provide workshops that intentionally build volunteer identity and sense of community within the organization. Insights from the psychology of volunteerism can be used to help address any number of important and pressing social issues, from poverty in local communities to problems that affect the entire planet like global climate change. The extent to which an issue can be affected and addressed by volunteers implicates the relevance of the psychology of volunteerism.

On a more theoretical level, the extent to which volunteerism can be linked to other prosocial behaviors can benefit the overall understanding of prosocial behavior by allowing the sharing of knowledge between domains of study. The tighter the link between volunteerism and forms of helping, the more useful models of volunteer behavior can be for understanding other forms of helping. The determining of the conditions under which volunteer behaviors are more or less likely to occur can improve the prediction of other prosocial behaviors. For example, by adopting the motivational approach used in research on volunteerism, perhaps studies of helping could consider helper motivation in order to determine the most effective ways for those in need of help to elicit assistance in work or school settings. The usefulness of research on volunteerism holds true not only for helping behaviors that, such as volunteering, are planned, sustained, and lack an obligation, but insights into volunteer behavior also have the potential to inform behaviors that are less commonly researched. These sorts of prosocial behaviors include the informal helping and emotional support one might receive from a barber while getting a haircut, or organizational citizenship behaviors such as whistle blowing. The usefulness of models of volunteer behavior, and the antecedents, experiences, and consequences of volunteerism, could also be applied to realms of behavior that are not always considered strictly prosocial behaviors, such as pro-environmental behaviors like recycling and conservation. Finally, hybrid national service programs, such as the Peace Corps and AmeriCorps, which straddle the line between work and volunteering, also stand to benefit from the knowledge generated by the psychological study of volunteer behavior.

In conclusion, psychological research has uncovered important contributors to the antecedents, experiences, and consequences of volunteerism for the volunteers serving, the recipients of help, and the organizations and communities through which volunteerism takes place. Contributors examined include demographics, personality, motivations, identity, past experiences, and the community context. These factors can help inform theoretical and practical extensions of the research, both in volunteerism in particular, and the wider prosocial literature.

Abstract

F.A. von Hayek is widely regarded as one of the most important economists of the twentieth century, as the most influential intellectual figure in the modern revival of classical liberalism, as a preeminent exponent of the Austrian School of Economics, and as the most articulate critic of socialist doctrines. He also deserves recognition as one of the preeminent social philosophers of the past century. In an age of increasing specialization within the social sciences and the humanities, he developed an approach to social analysis and social reform that integrates insights from economics, law, politics, philosophy, psychology, and evolutionary theory into an impressively coherent outlook at the foundations and evolution of social order. Hayek's scholarly writings span more than six decades and include numerous books and articles.

F.A. von Hayek is widely regarded as one of the most important economists of the twentieth century, as the most influential intellectual figure in the modern revival of classical liberalism (Kukathas, 1990), as a preeminent exponent of the Austrian School of Economics (Caldwell, 2004: pp. 17ff.), and as the most articulate critic of socialist doctrines (Caldwell, 1997). He also deserves recognition as one of the preeminent social philosophers of the past century. In an age of increasing specialization within the social sciences and the humanities, he developed an approach to social analysis and social reform that integrates insights from economics, law, politics, philosophy, psychology, and evolutionary theory into an impressively coherent outlook at the foundations and evolution of social order. Hayek's scholarly writings span more than six decades and include numerous books and articles, republished in *The Collected Works of F.A. Hayek* (1988).

Biography

Hayek was born in Vienna on 8 May 1899. Returning from service in the Austro-Hungarian army in World War I, Hayek enrolled at the University of Vienna and earned doctorates in Law (1921) and in Political Economy (1923). Interrupted by a year of study at New York University (1923–24), he worked from 1921 to 1926 as a legal consultant in a government office in Vienna, directed by his mentor Ludwig von Mises. Hayek's reading of Mises' (1922) penetrating critique of socialism and his participation in Mises' famous *Privatseminar* had profound influence on his thinking. Together with Mises he founded, in 1927, the Austrian Institute for Business Cycle Research whose director he was until 1931. When in 1929 Hayek became *Privatdozent* for Political Economy at the University of Vienna his *Habilitation* lecture, 'Gibt es einen Widersinn des Sparens?' (Hayek, 1929); English translation: 'The Paradox of Saving,' (1931a), in which he criticized the theory that business fluctuations are caused by 'underconsumption,' caught the interest of Lionel Robbins, the recently appointed head of the economics department at the London School of Economics (LSE). Recognizing that Hayek's critique was applicable to ideas that John Maynard Keynes had begun to promote in the late 1920s, Robbins invited Hayek to present a series of lectures on the Austrian perspective on business cycles at the LSE in early 1931. The lectures, subsequently published as *Prices and Production* (1931), were so well received that Hayek was offered the Tooke Chair of Economic Science and Statistics at the LSE (Ebenstein, 2001: pp. 172ff.), an appointment he held from 1932 to 1950. In 1950, he left England for the United States in order to take the position of Professor of Social and Moral Sciences at the University of Chicago's Committee on Social Thought. After retiring from Chicago in 1962, Hayek taught as Professor of Economics at the University of Freiburg, Germany, until 1969, when he accepted a guest professorship at the University of Salzburg. During his Salzburg tenure, in 1974, he was awarded the Nobel Prize in Economics. Yet, finding the expectations he harbored in returning to his native Austria disappointed, Hayek decided to return in 1977 as Professor Emeritus to Freiburg, where he spent the remaining years of his life. He died on 23 March, 1992. He is buried in Neustift am Wald, Vienna.

Economics and the 'Knowledge Problem'

Hayek (1967: p. 91) has said that the development of his thought was led 'from technical economics into all kinds of questions usually regarded as philosophical.' It was his early work on monetary theory, capital theory, and business cycle theory that earned him his appointment at the LSE, and it was about these themes that he engaged in controversies with John Maynard Keynes, Piero Sraffa and Frank H. Knight in the early 1930s. Although his 'Austrian' perspective on economic issues initially attracted considerable attention and earned him a reputation as the principal counterweight to Keynes, his fame began to decline in the mid-thirties. When he finally published his treatise *The Pure Theory of Capital* in 1941 it was so much overshadowed by the then dominant Keynesianism that it went almost unnoticed by the economics profession.

It was not only his disappointment at the declining attention he found in the profession that motivated Hayek to move away 'from technical economics.' An important turning point in his scholarly focus occurred in the mid-1930s, when he worked on an English edition of selected contributions to the 'socialist calculation debate,' which included Mises' early (1920) article

on the subject (Hayek, 1935). As Hayek noted in retrospect, when preparing this edition he began to develop a growing interest in the nature and unavoidable limitations of human knowledge; and he addressed the issue of what these limitations implied for theoretical efforts at understanding the social world and practical efforts at organizing social life. The concern with these questions, often referred to as the 'knowledge problem,' was to become the core theme of Hayek's lifework.

In Hayek's own assessment, the critical step in shifting his attention toward the broader issues of social theory and political philosophy was his 1937 article on 'Economics and Knowledge' (1948: Chapter 2), an article in which he addressed what he described as the 'central question of all social sciences,' the question of how the fragments of imperfect knowledge that exist dispersed in individual minds are coordinated in the social process to allow for productive cooperation among multitudes of persons. In his 1945 often cited article on 'The Use of Knowledge in Society' (1948: Chapter 4), Hayek restated and extended his earlier argument, stressing that the "problem of what is the best way of utilizing knowledge initially dispersed among all the people is at least one of the main problems of economic policy – or of designing an efficient economic system" (1948: pp. 78f.). In these two articles, which he considered his most original contributions to economics, Hayek developed a fundamental critique of two bodies of thought prevalent at the time – formal equilibrium economics on the one hand and socialist concepts of central planning on the other – censuring both of them for failing to account for the theoretical and practical difficulties that are posed by the imperfect, fragmentary, and dispersed nature of human knowledge.

In Hayek's view, the models of mathematical equilibrium economics provide only a pseudo-answer to the question that they are meant to illuminate, namely, how markets work. As he put it, with the "assumption of a perfect market where every event becomes known instantaneously to every member" (1948: p. 45), formal equilibrium analysis begs the very question that an empirically meaningful theory of market processes would have to answer, namely how "a solution is produced by the interaction of people each of whom possesses only partial knowledge" (1948: p. 91). Ironically, the failure committed in concepts of central planning is of a very similar kind. By assuming perfect knowledge on part of the planners, advocates of central planning provide only a pseudo-answer to the practical problem of how effective coordination of economic activities can be achieved in the absence of markets. The assumption that all relevant knowledge is available to, and can be administered by, a planning agency, raises the question of how such an agency is supposed to come to terms with the fact that much of the relevant knowledge "never exists in concentrated or integrated form, but solely as the dispersed bits of incomplete … knowledge which all the separate individuals possess" (1948: p. 77), i.e. knowledge that can be activated only by these very individuals.

What is needed, Hayek argued, is a theory that accounts for "the unavoidable imperfections of man's knowledge and the consequent need for a process by which knowledge is constantly communicated and acquired" (1948: p. 91). He called on his colleagues in the economics profession to turn their attention from the formal statements of equilibrium analysis to empirical "propositions about what happens in the real world" (1948: p. 46), propositions about how knowledge is actually acquired and communicated. Whereas his call did not find much response in the profession for a long time, in his own work Hayek himself pursued the research agenda that he had suggested. He specifically addressed the issue of how we acquire knowledge in his work *The Sensory Order – An Inquiry into the Foundations of Theoretical Psychology* (1952a), a most unlikely book for an economist and one of his least known works. However, it is, of great systematic significance for his entire work. In this book – which was in fact based on an early unpublished manuscript from Hayek's student days (Hayek, 2006[1920]) – Hayek developed a theory of the human mind, the essence of which, as has been recognized by renowned experts in the field (e.g., Fuster, 1995: pp. 87ff.), is in amazing accord with modern cognitive and neurological science. Seeking to explain how the human mind establishes its connections "between the input of (external and internal) stimuli and the output of action" (1982: p. 288), Hayek interpreted the working of the mind as an adaptive process of constant classification and reclassification on many levels (sensory perceptions, emotions, concepts), a process in which conjectural internal models of the outside world are adaptively formed and guide actions.

The issue of how knowledge is communicated and advanced in society is at the core of Hayek's theory of the market as a communication system (1976: Chapter 10) and of competition as a discovery procedure (1978: Chapter 12) – a theory that formed the centerpiece of his work. The prices formed in the competitive market process, Hayek argued, signal to all market participants the relevant general information about changes in relative scarcities that they need to know about in order to adjust their behavior adequately, utilizing their unique local knowledge of the particular circumstances of time and place. This type of knowledge could never be communicated to, or utilized by, a central planning agency. Beyond serving thus as a device for utilizing dispersed knowledge, the market serves also as an arena for the continuous competitive exploration of new and potentially better solutions to economic problems, thus inducing the discovery and creation of new knowledge.

Spontaneous Order and Evolution

The relevance of Hayek's work, not only for economics but also for the social and behavioral sciences more generally, is most clearly visible in his theories of spontaneous social order and cultural evolution, which he developed as generalizations and extensions of his arguments on market processes and competition. The thrust of these theories is that human societies are highly complex phenomena and that the processes of social coordination and societal evolution are inappropriately simplified and misconceived if they are approached in the spirit of the mechanistic models of physics (1952b). Criticizing as 'scientism' the misguided ambition to model the social sciences in the image of physics, Hayek argues that "when we turn from mechanical to such 'more highly organized' or essentially complex phenomena as we encounter in the realms of life, mind and society" (1973: p. 41), all we can reasonably hope to

achieve are *explanations of the principle* and *pattern predictions*, rather than explanations or predictions of specific events (1967: Chapter 2). Hayek added that the 'hard' sciences would also be subject to these limitations as their advance "penetrates further and further into complex phenomena" (1967: p. 20). Hayek argued that the theory of evolution by natural selection exemplifies in a paradigmatic manner what is true for all theories of complex phenomena, – namely that they provide "an account of a process, the outcome of which will depend on a very large number of particular facts, far too numerous for us to know in their entirety" (1967: p. 23). He posited that even if we know the general laws according to which complex phenomena operate, our lack of knowledge of all the particular facts by which they are affected prevents us from obtaining anything more than an explanation and prediction of "the abstract pattern the process will follow" (1967: p. 23).

Hayek placed his own social theoretical outlook in the tradition of the Scottish moral philosophers (notably Adam Ferguson, David Hume, and Adam Smith), whom he credited with the discovery of "the twin concepts of the formation of spontaneous orders and of selective evolution" (1988: p. 146). Central to this paradigmatic tradition is a methodological individualism and subjectivism, that is, on the one hand, the notion that social aggregate phenomena are, ultimately, to be explained in terms of the actions and interactions of individual human beings and, on the other hand, the insight that "the analysis of what people do can start only from what is known to them" (1948: p. 44); that is, from their subjective view of the world. Equally central is the notion that the productive coordination and division of labor that we observe in society, as well as the rules and institutions on which societal cooperation is based are not due to deliberate planning and conscious design, but to forces of spontaneous mutual adjustment and evolution. From these premises, Hayek drew important conclusions on the limits of our ability to improve our social condition by deliberate construction.

According to Hayek there are, essentially two categorically different ways in which the actions of individuals can be socially coordinated – either through spontaneous mutual adjustment within a framework of general rules of conduct or through the commands of a central 'planner' (1973: Chapter 2). The respective merits and limits of these *two kinds of order* – *spontaneous order* and *organization* (Vanberg, 1982) – are rooted in the nature of the principal means by which the coordination of actions is achieved, namely by general rules in case of the former and specific commands in case of the latter. Command-based organization is an effective method of social coordination where specific, limited purposes are to be achieved. Because of its reliance on central coordination it is, however, severely limited in its capacity to utilize the knowledge dispersed among its individual participants. By contrast, the advantage of rule-based spontaneous social orders is that, by allowing individuals to pursue their own ends within the general confines defined by the rules, they can utilize and activate localized, dispersed knowledge to a much higher degree. The price that has to be paid for their greater capacity for utilizing knowledge is that the *particular* outcomes that they generate must inevitably remain largely unpredictable. In Hayek's view, the respective merits and limits of the two kinds of order should lead us to conclude that, while organization can be a useful method for solving a multitude of specific, limited tasks, it cannot possibly be appropriate for the extended order of an economy or a society at large. There is ample room for organizations within the spontaneous order of society, but efforts to turn society itself into an organization can only end in disaster.

An important element in Hayek's theory of spontaneous social order is the insight that, while the particular outcomes of a rule-based order remain necessarily largely unpredictable, the general pattern of its outcomes is determined systematically by the nature of its rules. There exists, Hayek emphasizes, a systematic interplay between the 'order of rules' and the 'order of actions' (1967: Chapter 4) – between the nature of the 'rules of the game' on which the interactions of the participating individuals are based and the nature of the action-patterns that emerge from the individuals' behavioral choices within the rules. To the extent that we understand how the *order of rules* affect the *order of actions* we can predict the general nature of the behavioral patterns that will emerge within particular rule-frameworks, just as an understanding of the rules of a sport allow us to predict, if not particular outcomes, the general pattern of moves that we can expect to observe on the playing field. Hayek argued that in fact, our knowledge of the systematic relationship between the order of rules and the order of actions is the primary instrument that we can employ to improve our condition. This knowledge enables us to choose 'rules of the game' that can be expected to generate more desirable overall patterns of outcomes in the various social arenas in which we interact with each other.

Hayek's emphasis on the basic fact of 'the dispersion and imperfection of all knowledge' led him to be highly critical of the mind-set that he labeled 'rational constructivism' or 'constructivist rationalism' (1978: Chapter 1). Under this rubric, he subsumed approaches to issues of social policy and social reform whose recommendations are based on a 'pretence of knowledge' (1978: Chapter 2), that is, on unjustified presumptions concerning the extent of our knowledge and our intellectual powers. The primary targets of Hayek's critique were approaches that, like socialist concepts of central planning, amount to the "claim that man can achieve a desirable order of society by concretely arranging all parts in full knowledge of all the relevant facts" (1967: p. 88). Against such claims, Hayek pointed out that, because it is simply impossible for us to take "conscious account of all the particular facts which enter into the order of society" (1973: p. 13), we need to rely on general rules "as the means to create order in social affairs" (1948: p. 19), and our efforts at building a better society must largely rely on the indirect method of improving the rules and institutions under which we live, instead of on attempts to directly produce desired outcomes through specific interventions.

Hayek stressed that in our efforts to improve the framework of rules and institutions under which we live, we need to be careful to avoid the pitfalls of a pretense of knowledge. Since the desirability of the outcome patterns that particular rules or institutions tend to generate can only be judged appropriately in terms of their working properties over extended periods of time, it would be presumptuous to claim that we can easily design, at the drawing board, rules and institutions that serve us better

than those that have evolved over generations. Just as the process of competition in ordinary markets, by allowing alternative potential solutions to be tried out, helps us to discover how our various 'economic' problems can be solved better than before, so competition in the realm of rules and institutions can serve the function of testing the kinds of rule arrangements that provide more conducive conditions for mutually beneficial cooperation among multitudes of persons. A process of competitive selection can here, just as in ordinary markets, help gradually to evolve solutions that are much more effective than those that any rational design could have ever invented at the outset. In fact, so Hayek argues, the institutions on which our civilization rests, including the rules of the market, should be viewed as the outcome of the process of cultural evolution that extended over innumerable generations and incorporated the experience of many more trials and errors than the wisest and most intelligent rule designer could ever consider. Our efforts at institutional reform and rule design should, therefore, always be informed by a respect for the potential wisdom implicit in inherited institutions, and we should expect further improvement "more from slow experimental piecemeal evolution than from redesign of the whole" (1964: p. 8).

The theory of cultural evolution is the theme to which Hayek devoted much of his later work (see Epilogue in 1979; 1988), and it is this part of his theory that has become a primary focus of discussions on his ideas. A central issue in these discussions is how the notion of competition among institutions – a notion that is at the heart of Hayek's ideas on cultural evolution – is to be specified; under what conditions can such institutional competition be expected to generate 'good' rules, that is, rules with working properties that are desirable for those to whom they apply (Vanberg, 1994a: Chapter 5; 1994b).

Liberalism and Democracy

A central theme in Hayek's political philosophy is the relation between liberalism and democracy (Vanberg, 2011). Hayek pointed out (1978: p. 142) that by its "insistence on a law which is the same for all and the consequent opposition to all legal privilege," liberalism was originally closely allied with the democratic ideal of equal rights in political participation, so that in "the struggle for constitutional government in the nineteenth century the liberal and the democratic movement indeed were often undistinguishable" (1978: p. 142). In Hayek's account, the two movements parted company after the victory of democracy, when the erroneous belief came to prevail "that the adoption of democratic procedures made it possible to dispense with all other limitations on government power" (1979: p. 3), thus fostering a concept of democracy that regards "current majority opinion as the only criterion for the legitimacy of the powers of government" (1978: p. 143). The organizational form in which this concept has become institutionalized (which he describes as 'unlimited democracy') is in Hayek's view incompatible with the liberal ideal of limited government according to which "it is not from a mere act of the momentary majority but from a wider agreement on common principles that majority decision derives its authority" (1960: p. 106). It is also in conflict with the "true content of the democratic ideal" (1979: p. 5) because it inevitably results in a policy that instead of serving the *common interests of the citizenry*, gets entrapped in being lobbied by special interests and granting privileges to them. "The reason is," Hayek noted, "that democratic government, if nominally omnipotent, becomes as a result of its unlimited powers exceedingly weak, the playball of all the separate interests it has to satisfy to secure majority support" (1979: p. 99).

As a remedy for the deficiencies of unlimited democracy Hayek advocates a *constitutional conception of democracy* that insists on the role of a *limiting constitution*, i.e., on the understanding that all democratic power derives from "the consent of the people" (1979: p. 3), and its legitimacy rests "in the last resort on the approval by the people at large of certain fundamental principles underlying and limiting all government" (1979: p. 35). Of utmost importance are, in Hayek's assessment, constitutional limitations that prevent discriminatory politics by effectively restricting the authority of government and the legislature to grant special privileges to interest groups. Hayek argues that rather than weaken the effective power of the democratic state, such restrictions would strengthen its ability to fulfill its true task, namely to advance the *common interest* of its citizens. As a significant step toward an effective limiting constitution Hayek advanced a proposal for constitutional reform (1979: pp. 105ff.) that is based on the diagnosis that a major defect in the prevailing institutional structure of democracy must be seen in the fact that one and the same representative body, the parliament, has been entrusted with two fundamentally different tasks – on the one hand, to establish the 'rules of the game,' or the laws on which society and state are based and, on the other hand, to direct the day-to-day operations of the particular government. As Hayek charges, the inevitable effect of assigning these two tasks to one and the same assembly has been "that the supreme governmental authority became free to give itself currently whatever laws helped it best to achieve the particular purposes of the moment" (1979: p. 101). In this short-sighted approach to legislation, he sees the main reason why such an assembly must become the target of the lobbying efforts of interest groups and finds itself pressured to "use its power to satisfy the demands of sectional interests" (1978: p. 115).

According to the 'model constitution' that Hayek proposed, the two noted tasks are to be assigned to two strictly separated representative assemblies, with the separation to be institutionalized in a manner that can effectively "prevent collusion of the legislative with a similarly composed governmental assembly, for which it would be likely to provide the laws which that assembly needed for its particular purpose" (1978: p. 160). Hayek's ambition to specify in considerable detail the modes in which elections to the legislative assembly ought to be organized had the unfortunate effect that critical reactions to his constitutional proposal almost exclusively concentrated on its subordinate details; whereas his primary concern, the effective separation between genuine legislation and day-to-day government, did not find the attention it surely deserves.

Impact and Significance of Hayek's Work

With his arrival at the LSE in the early 1930s, Hayek became almost instantaneously a well-recognized figure in the

economics profession, engaged in prominent controversies on economic theory with such opponents as John Maynard Keynes and, on the issue of rational economic calculation under socialism, with Oskar Lange and others. When his involvement in the latter debate, induced the shift in his interest toward general issues of social and political philosophy, he increasingly removed himself from standard professional discourse. He turned his attention to a fundamental critique of the philosophical foundations and the political implications of socialist doctrines. This was reflected most prominently in the publication of his most famous book *The Road to Serfdom* in 1944, a book that quickly made him a widely known public figure, in particular in the United States, where a condensed version appeared in the *Reader's Digest* in 1945. While the book earned him public fame, it was met much less favorably by his colleagues in the economics profession, many of whom were, at the time, much more inclined to interventionist views than to Hayek's warnings against socialist concepts of social and economic planning. Feeling the need to form a closer network among the dispersed and often isolated advocates of classical liberalism, Hayek in 1947 brought together a group of like-minded colleagues from various disciplines to a conference at Lake Geneva in Switzerland, which was to become the founding meeting of the Mont Pèlerin Society.

With the rise of Keynesianism in the 1950s and 1960s, Hayek's work fell almost into oblivion, in academia as well as in public debate. When in 1960 his major restatement of the principles of classical liberalism, *The Constitution of Liberty*, appeared, it was widely regarded, even by sympathetic observers, as an outdated treatise, out of step with modern economic and political thought. It came as a surprise to many, including Hayek himself, when in 1974 he was awarded the Nobel Prize in Economics. Even if the fact that he had to share the prize with Gunnar Myrdal (an economist of a quite different orientation) reflected significant ambivalence on part of the Nobel committee, the award was an early indicator of a reawakening interest in classical liberal thought in general, and Hayek's work in particular; an interest that grew significantly in the latter half of the 1970s, as a response to an increasing disillusionment with Keynesian economic policies and the accumulating evidence of the failure of 'real socialism.' In fact, Hayek became very much the symbol of what has been described as the 'modern rebirth of classical liberalism.' His work regained increasing attention in the academic community, his ideas influenced politicians like Margaret Thatcher and Ronald Reagan, and his publications found growing interest among dissidents and reformers in the disintegrating Communist world. Hayek lived long enough to witness the final collapse of the Communist regimes in Europe as a confirmation of his lifelong critique of socialist constructivism.

In modern theoretical economics, Hayek's ideas play an important role in a number of approaches that seek to advance an alternative theoretical outlook to the orthodox equilibrium paradigm. His ideas on the nature of human knowledge and learning are finding increasing attention among scholars who seek a corrective for the deficiencies of the traditional rational choice model. Developments in evolutionary economics, in the new institutional economics, and in the economics of complex adaptive systems, either explicitly draw on, or give support to, core ideas of his work, to his theory of the market as a spontaneous order, his outlook on competition as a discovery procedure, and his evolutionary approach to institutions.

Even if the reception of Hayek's work in social sciences other than economics remains quite limited, his approach to social theory may well come to play a significant role as a paradigmatic contribution toward a theoretically integrated social science. It was one of Hayek's major concerns that the disciplinary fragmentation of modern social science left what should be its central issue, namely "the problem of an appropriate social order," without adequate attention. As he put it, even though this issue "is studied today from the different angles of economics, jurisprudence, political science, sociology, and ethics, the problem is one which can be approached successfully only as a whole" (1973: p. 4). More than any of his contemporaries in the social sciences, Hayek in his own work, made an effort to address the fundamental issue of an 'appropriate social order' from a general social theoretical perspective that cuts across traditional disciplinary boundaries. With his ideas on the two kinds of social order, on the function of rules and institutions, and on cultural evolution he took important steps toward a theoretically integrated social science.

Abstract

Alexander von Humboldt (1769–1859) made essential contributions to a variety of disciplines and branches of knowledge, namely astronomy, geography, mineralogy, electrophysiology, political sciences, cartography, colonial history, and cultural anthropology. Humboldt's understanding of nature as a system of dynamic and interrelated phenomena, based on empirical studies, puts an end to natural history as a branch of philosophical speculation and stands at the threshold of modern science. Its roots can be traced from his American oeuvre until the *Kosmos*. His abundant reflections on the history of European colonization as well as his attempt to develop global comparative studies of natural phenomena have recently been presented as an important element in the history of globalization discourse.

Humboldt, Alexander von (1769–1859)

Alexander von Humboldt, likely the most famous European naturalist and scientific traveler in the nineteenth century, made essential contributions to a variety of disciplines and branches of knowledge, namely astronomy, physical and applied geography, geodesy, mineralogy, electrophysiology, political sciences, cartography, colonial history, and cultural anthropology. Several fields of study emerge from Humboldt's works: plant (or phyto-)geography, pre-Columbian studies, political geography, and modern climatology. Humboldt's understanding of nature as a system of dynamic and interrelated phenomena, based on empirical studies, puts an end to natural history as a branch of philosophical speculation and stands at the threshold of modern science. Three titles of Humboldt's vast oeuvre stand out the most to represent the literary and aesthetic significance of his works: the *Relation historique* (Personal Narrative) describes his American travels in the genre of scientific travel literature, and the other two, namely *Ansichten der Natur* (Views of Nature) and *Kosmos*, are the key elements of his reformist efforts of democratizing knowledge, inspiring a sway of popular science books in the second half of the nineteenth century.

Today, his reflections on the interconnectedness between human settlement and natural resources are gaining attention of studies on historical climate change, biodiversity, and ecocriticism. His abundant reflections on the history of European colonization as well as his attempt to develop global comparative studies of natural phenomena have recently been presented as an important element in the history of globalization discourse. Humboldt's holistic model of science is considered as a precursor for today's transdisciplinary approaches. It represents an intellectual practice of connecting and intertwining different norms and formations of knowledge, with a coherent pattern traceable from his American oeuvre until the *Kosmos*.

Youth, Education, and European Travels (1769–99)

Not all of this was evident right from the start. Born on 14 September 1769 at Berlin, Humboldt's youth was largely characterized by early failure, physical delicacy, and frustration. Apparently less brilliant and less motivated than his older brother Wilhelm, Alexander had to endure the long hours of instruction from many of, indeed first class, private educators that frequented Schloss Tegel in his early years. At the age of 16, the first visits to Henriette Herz's progressive salons put an end to the deprivation Alexander had felt so strongly, and introduced both the brothers to the brightest minds of the enlightened Berlin. The following years were dedicated to the study of cameralism, economics, natural history, mathematics, anthropology, physics, and languages at Frankfurt/Oder, Göttingen, and Hamburg. Nevertheless, it was another discipline, botany, that attracted his main attention in these years. His first mentor, the Berlin botanist Carl Ludwig Willdenow, introduced Alexander to his collection of exotic specimen from the tropics. Soon, the inspiring sessions with Willdenow boosted his desire for expedition, travel, and first-hand experience. During a stay in Mainz he was introduced to Georg Forster, who would become his travel companion on a voyage through Europe in 1790. It was with Forster, a member of the second Cook expedition, that Humboldt not only witnessed the revolutionary energy of Paris, but also the cosmopolitan spirit of London, where he met Sir Joseph Banks and attended sessions at the Parliament. These weeks were to become crucial for the initiation of the adventurous, the ambitious and the political Humboldt – the restless traveler, prolific author, and future diplomat.

Back in Prussia and after completing his studies of mineralogy at the famous Bergakademie Freiberg (1791–92), Humboldt was all prepared for a promising career as Prussian mining director. His instructive manuals and practical inventions soon led to major improvements in the productivity and working conditions of the mines he supervised. Experiments in electrophysiology and the chemistry of plants were to follow, spreading his name in the scientific community of his days. In search of the 'forces of life' (*Lebenskräfte*), Humboldt developed the idea of the harmony of elements in the inner organization of all living organisms, a concept that fully crystallized in a famous note he would jot down in his American travel diary in 1800: 'Everything is interrelated' (*Alles ist Wechselwirkung*). This conviction marks the epistemic nucleus of the Humboldtian approach, which also shaped the *Kosmos* in the notion of 'nature is unity in diversity' (*Natur ist Einheit in der Vielheit*). Unsurprisingly, the first sketches for a 'physical description of

the world' (*physique du monde/Physikalische Geographie*) date back to these days.

The year 1796 marked a turning point in Humboldt's early career. With the death of his mother, Alexander inherited a large fortune, providing means for realizing his aspiration for scientific expedition. He immediately resigned from his public offices and from there on, his every activity was conceived as preparatory: acquiring only the finest scientific instruments, networking in Paris (with Delamétherie, Borda, Delambre, Laplace, Lamarck, and Cuvier), finding a travel companion (the French physician and botanist Aimé Bonpland), measurements, travels through Spain, new measurements, and finally, soliciting a travel pass through the Americas from King Carlos IV. With diplomatic skill and the backing of the Spanish minister Urquijo, the petition succeeded. On 5 June 1799, Humboldt and Bonpland set off from the port of La Coruña to American shores: the first independent travel expedition in modern times was about to begin.

The American Voyage and the Years in Paris (1799–1829)

"We run around like fools; during the first three days, we did not identify a thing, always dropping one object to pick up another one. Bonpland claims that he will loose his mind if the marvels do not stop soon. But even more beautiful than each of these wonders by itself is the impression of the entirety of this powerful, luxuriant and at the same time so light, cheerful, and mild plant life. I feel that I will be very happy here and that these impressions will continue to cheer me in the future" (Humboldt in Kutzinski et al., 2012).

In this first letter from the *New Continent*, as he liked to phrase it, Humboldt puts in a nutshell the fascination he would feel for the tropics through his entire life. These lines, written to his brother Wilhelm on 16 July 1799 from the Venezuelan port of Cumaná, seem to inscribe Humboldt into the tradition of Spanish chronicles from the conquista days, when America's nature (and people) were miraculous, exotic, and exuberant. But Humboldt's American Voyage was never aimed at 'marvelous possessions' (Greenblatt). The gaze at beautiful wonders soon gave way to thorough science in the field – countless measurements on ships and donkeys, in valleys and on mountain peaks, research in the colonial archives and at archeological sites, and an ever-increasing specimen collection of America's flora and fauna.

The 5-year voyage (1799–1804) had the travelers depart from Spain for a stopover in the Canary Islands to land at the coast of the Venezuelan provinces, traverse the *hinterland* of New Granada, Cuba, Cartagena, the South American Cordilleras, Bogotá, Quito, Lima, Guayaquil, New Spain, Cuba again, and for a last brief stop, the United States, before returning to Europe. He came into contact with all social classes of the Spanish colonial world: Spanish officials, European merchants, indigenous servants, workers and peasants, enslaved Africans, catholic missionaries, and creole elites from all branches of society: politics, economics, culture, and academia. He ascended many of the most prominent mountains and volcanic peaks of the continent, among them Mount Chimborazo near Quito, then considered the highest summit in the world. In 75 days, he traveled 1500 miles in a pirogue, up and down the Orinoco, Meta, and Casiquiare Rivers, lending final proof to the older hypothesis of an intricate connection between the Orinoco and Amazonas network. His interests and research encompassed botany, zoology, climatology, geology, economy, cartography, political geography, and cultural history of the 'New Continent' (**Figure 1**).

After his return to Europe, Humboldt undertook several journeys to complete his American antiquarian research, among them a sojourn in Rome, where he would meet his brother Wilhelm and undertake a 'voyage d'archive' (Bourguet, 2011) through the Vaticane codices in search of Mesoamerican manuscripts. Already an international star of science, Humboldt was faced with a general public curiosity for his travel accounts and the European *République des lettres*, awaiting the results of his scientific findings. The very successful *Ansichten der Natur* (Tübingen 1808) fulfilled the expectations of the former. Their colorful and vivid descriptions of the American landscapes combined literary composition with a naturalist framing, introducing Humboldt's concept of a physiognomy of nature.

Publishing in Paris

Even though the 1st edition of *Ansichten* was all about his American journey, Humboldt did not consider them to be part of the 29 volumes that he would publish in the following decades upuntil 1838, when the last part of Humboldt's history of colonial discovery, the *Examen critique*, was to appear in Paris. His American oeuvre was aimed at his peers and targeted two goals: to deliver specific studies, findings, and measurements to the specialized scholar, and to provide, at the same time, a general and all-encompassing tableau of the physical, political, and cultural character of the tropics. Publishing most of his American works from Paris also meant publishing them in French, a matter of course for Humboldt, who had been raised bilingually from his earliest youth. Needless to say, it is the French capital, where Humboldt's scientific ambitions were to find their most natural habitat. Paris would become the center of his life from 1809 to 1827 and a frequent place to return to, whether in private or on a diplomatic mission with assignments from the Prussian King. The city offered all he needed: the most renowned institutions of science and culture, and the best publishing houses for his demanding task to produce his findings in opulent quarto and folio volumes. Some of Humboldt's plans were to fall short of his own expectations, especially his time frame: instead of 3 years, he needed 30 years for the project, the simultaneous publication of all his writings in both French and German had to be abandoned soon in favor of the French, his *Relation historique* despite taking almost 20 years in the making was never completed, and several intents to publish revised editions of some of his titles failed in the light of more urgent matters.

In his times, only comparable to a work like the *Description de l'Égypte*, Humboldt's *Voyage aux régions équinoxiales du Nouveau Continent* is abundant in its content and, at times, puzzling in its complex network of references. It can certainly best be described by the impact its various publications left on the contemporary academic and political landscape.

As one of its earliest outcomes, Humboldt's *Essay on the Geography of Plants* (Paris, Tübingen 1807, Trans. Humboldt and Bonpland, 2009), became a founding document for the

Figure 1 Map of Humboldt's American travel route. Original file from: Wikimedia Commons (http://en.wikipedia.org/wiki/File:AvHumboldts_Americatravel_map_en.svg) The file is licensed under the Creative Commons Attribution-Share Alike 2.5 Generic license.

comparative study of plants in their spatial and climatic distribution, articulating an integrative science of the earth, which encompasses most of today's environmental sciences (Jackson, 2009). The iconic image of this newly drafted discipline – the 'Physical Tableau of the Equitorial Regions' – was likely its main attraction (**Figure 2**). Much more than an illustration to the text, the 'tableau' functions as a visualization of the discipline itself, its intellectual ambition, and (inter-) disciplinary scope. Both in the book and in the 'tableau' itself, Humboldt first experimented with a conceptual framing of dialogue between text and image that later became the cornerstones of his geographic, political, and cultural atlases (Kraft, 2014). Together with applying geological profiles formerly used in mining to outline the physical character of territories like Spain and Mexico, these visual breakthroughs put Humboldt's name among the most innovative examples of data visualization in the nineteenth century. Humboldt's both theoretical and visual concepts of isothermal lines provided cartographic representation to climate research, an innovation that is still in use today. With Humboldt's isotherms, worldwide comparative climatology became pictorial.

The Political Humboldt

Recently, more attention has been given to the political side of Humboldt's oeuvre. For a Latin American audience, this is, of course, nothing new. His two major writings *Political Essay on the Kingdom of New Spain* (Paris 1808–11/1825–27, Trans. Humboldt, in press) and *Political Essay on the Island of Cuba* (Paris 1826, Trans. Humboldt, 2011) played a major role in the struggle for independence during the first decades of the century. For Humboldt's voluminous text on New Spain, this is even more true as he composed and published his writings and substantial cartographic material on New Spain on the eve of its final decline, that is, just at the moment, when the creole elites were to initiate national liberation from the Spanish dominion. Humboldt, in the history of his reception often coined as the 'second,' that is, the 'scientific discoverer of America,' was thereby enthroned as the programmatic precursor of future Mexico. The Mexican historian and politician Lucas Alamán left no doubt about the foundational character of Humboldt's work when he wrote to Humboldt that the constitutional assembly of 1824 used his *Political Essay* as inspiration and guidance for the tasks ahead. Clearly, both texts – as much his study on New Spain as the one on Cuba – were to set new standards by their concise study, composition and presentation of geography, politics, economics, demography, and social analysis of the colonies. Humboldt's essays gave way to new American self-awareness: up-to-date in its data – gained from proper measurements, from thorough work in the archives, and contributions from his countless correspondents – independent in its judgment and overwhelmingly precise in its cartographical mapping.

In Cuba, matters were different: his work was censured on the spot, and independence far away. The censorship was largely due to Humboldt's crystal clear stand on the issue of slavery, undoubtedly the foremost topic in sociopolitical, economic, and ethical debates in nineteenth-century Cuba. In 1791, the enslaved in the French colony of Saint-Domingue had begun the first successful large-scale insurrection in history, known as the Haitian Revolution (1791–1804). With Saint-Domingue's economy in ruins, the demand for Cuban sugar increased, and so did Cuba's demand for slaves. In addition to infusing the Cuban sugarcane industry with thousands of fleeing French planters and sugar engineers, the Haitian Revolution also generated widespread fears of another revolution. During his two visits to the island (1800–01/1804), Humboldt gained a close impression of the shock-waves that the Haitian Revolution had left among the Cuban oligarchy. He mentions the 'troubles in Saint-Domingue' repeatedly in the *Political Essay on the Island of Cuba*, pointing to the progressive agenda that Havana's merchant guild and Patriotic Society had pursued in the 1790s and again in 1811. But that did not much improve the working conditions of Cuba's enslaved, whose fate – as Humboldt had argued – could only lie in the complete abolition of slave labor. However, the book was to take another turn in its international reception. In 1856, the US journalist, pro-slavery activist, and intimate expert in Cuban affairs, John S. Thrasher, published an English translation of Humboldt's text. In *The Island of Cuba*, Thrasher had made significant changes, omitting Humboldt's section on slavery and making countless emendations that Humboldt himself saw as 'politically motivated.' In the eyes of the English reader, Humboldt had turned from a vehement abolitionist to a mild reformer with sympathies for the ruling oligarchy of sugar planters. That same year, Humboldt complained about Thrasher's manipulations in a public letter that was immediately translated to English and appeared in numerous newspapers across the U.S. The affair was even to influence public opinion during the Presidential campaign between James Buchanan and the Humboldt admirer John C. Frémont. Humboldt's fierce denials in this scandal should have restored his reputation, but in fact, the stain of political opportunism or even reactionary blindness to social problems would remain with the (English-speaking) readership until the recent times.

The Mesoamerican Cultures

What has been called Humboldt's 'imperial gaze,' in other words his contribution to the imperial politics of the late nineteenth century, can also be read as late reflexes of this (at times intentional) misreading. Yet it is not coherent with either his political or his cultural-anthropological writings. On the contrary: Humboldt's political criticism went far beyond that of most of his contemporaries. In his *Political Essay on the Kingdom of New Spain*, he openly condemned the Mexican creole elites and colonial administration for their complete lack of political vision and inaptness to guarantee legal equality to the indigenous populations. In his *Political Essay on the Island of Cuba*, as outlined in the preceding paragraphs he strongly rebuked the agroeconomic complex of mass slavery and monocultural plantations. In both texts, as well as in countless political activities during his lifetime, he argued for political reform both in the Americas and in Europe, in favor of individual freedom, political participation, and liberal economics. Among the first Europeans in nineteenth century to thoroughly study the archeological remains of Mesoamerican cultures, Humboldt made seminal contributions to the cultural history, mythology, and archeoastronomy of the Americas in his 'pittoresque atlas,' the *Views of the Cordilleras and Monuments of the Indigenous*

Figure 2 Tableau physique des Andes et Pays voisins.; Humboldt, A. von, Bonpland, A., 1807. Essai sur la Géographie des Plantes accompagné d'un tableau physique des régions équinoxiales. Fondé sur des mesures exécutées, depuis le dixième degré de latitude boréale jusqu'au dixième degré de latitude australe, pendant les années 1799, 1800 1801, 1802 et 1803. Avec un planche. Peoples of America (Paris 1813, Trans. Humboldt, 2012a). As an early example of nineteenth century anthropology and ethnology, Humboldt's keen interest in indigenous cultures helped to shed a new light not just on the remains of perished societies, but also on the originality of Native American art, sparking "a movement to reconsider the aesthetic value of non-European art that eventually led to a new, 'modern' aesthetic'" (Kutzinski et al., 2012). Humboldt's American nature, in consequence, is not a vast territory of unpopulated land ready to become the object of European desires, as some have suggested, but a space of complex histories, layers of time, and language(s), that Humboldt not only reflects upon in his text, but also visually in his American cartography.

The American oeuvre, encompassing 29 volumes with over 1400 copper plates, was to become the largest and the most expensive scientific work a single person had and has ever published. Its impact reached two continents, ruined several publishing houses, and finally, Humboldt's finances as well. This was one of the reasons why he saw himself forced to leave his beloved Paris to return to Berlin in 1827 and take an appointment by his King, Friedrich Wilhelm III, to serve as chamberlain at the Prussian court.

The Russian–Siberian Voyage (1829)

By that time, his plans for an expedition through Russia and Siberia had become very determined. The first sketches of this research program date back to 1812. Already then, Humboldt knew that the major tasks of his scientific masterplan were still ahead. In order to conceive the physical world as a cosmos of forces, natural phenomena, and relations, Humboldt needed an Asian counterpart to his American experience. But unlike during his travels through the 'New Continent,' Humboldt had become too famous and financially too dependent to undertake such a mission on his own. As head of a group of naturalists (Humboldt, Christian Gottfried Ehrenberg, and Gustav Rose), Humboldt had to follow a predefined travel route, with welcoming committees at every station, close surveillance by Cossack horsemen and a clear division of labor, in which his own contribution was strictly limited to mere scientific output. The reputation of Humboldt's political stance over questions of individual liberty, peonage, and social reform seemed too much of a risk for the Russian Emperor Nicholas I. Humboldt's acceptance of these hard-to-bear conditions can only be explained by the credo of his global comparative project, for which the travels to Central Asia were essential. Already 60 years of age, he knew that such an opportunity was improbable to come again. The travels became an Asian *tour de force*, with halts in Königsberg, Riga, Saint Petersburg, Moscow, the Urals, Altai Mountains, a gaze at the Chinese borders, the great Siberian planes, Omsk, the Caspian Sea, the return to Moscow, and, finally, Berlin. In just about 9 months, the expedition had traveled more than 10 000 miles, mostly at night. Restricted as he was in his scientific endeavors, Humboldt focused on magnetic, barometric, and astronomic findings, mining enterprises, and comparative analyses between the American and Asian nature. In the 30 years between his first and the second great voyage, much had changed. As Humboldt stated in a letter to Wilhelm from September 1829, the remarkable pace of his second *grand tour* correlated with the acceleration of modern science, better instruments, and the refinement of methods in all branches of knowledge. Yet despite the modern times, it would take him another 14 years to complete his studies and accommodate the results of the Russian–Siberian Voyage in the three volumes of *Asie Centrale* (Paris 1843). They were to pioneer the era of modern geology on Inner Asia.

The Final Chapter: Scientific Networks and Humboldt's *Kosmos* (1829–59)

Already in 1828, Humboldt had started to build new scientific networks in the Prussian capital. A conference under his direction brought together 600 naturalists and physicians in Berlin, where he initiated numerous activities to propel the city's academic culture and foster new scientific institutions. The goal was as clear as it was ambitious: Humboldt wanted Berlin to become a centerpiece place of modern science. His 'Kosmos lectures' at the University and the Singakademie were to attract crowds of more than 800 people eager to hear Humboldt's lessons on the general aspects of the physical world ('Allgemeines Naturgemälde'). Even though related to the successive appearance of his *Kosmos* from 1845 to (posthumously) 1862, the lectures have to be seen more in the light of raising public awareness for scientific knowledge and education. The idea of the *Kosmos* as a stand-alone work in its own right dated back much earlier, envisioned decades before the lectures in his *Geography of Plants* and fully conceptualized in a letter to his friend Karl August Varnhagen von Ense in 1834. The 'work of my life' was meant to embrace it all and "present an epoch in the mental development of man as regards his knowledge of nature" (Humboldt and Varnhagen von Ense, 1860). Humboldt's goal was to satisfy both: the specialist and the general public, the professor and the student. As the first tranches of *Kosmos* were to appear in 1845, readers' expectations had risen to unprecedented levels. By the time the second volume became available, German booksellers were overrun by public demand and had to commission multiple reprints. British and US-American publishers competed with three simultaneous editions, while rushing to present new and updated translations of the *Ansichten der Natur* and the *Personal Narrative*. *Kosmos* was to become the popular epitome of Humboldtian thinking: modeling nature in its inherent connectivity, its network-like, organic intertwinement, and, finally, in its relation to man. "For the study of nature was, for Humboldt, inseparable from the study of the mind in its material, social, and cultural context. This reflexivity of mind, society, and nature became his overriding argument" (Walls, 2005).

Humboldt was not to see the final volume of his *Kosmos* published, when it finally came out in 1862. Quite literally with the quill in his hands, he died on 6 May 1859, at the age of 89, in Berlin.

The Present: Proliferating Humboldt Studies, New Editions, the American Travel Diaries

Current studies on the life, works, and scientific achievements of Alexander von Humboldt encompass a wide array of disciplines and scholarly fields (history of science, colonial history, postcolonial studies, art history, cultural studies, poetics of science, history of ideas, epistemology, environmental studies,

and ecocriticism). What we might call a rather recent *renaissance* of Humboldt studies is largely due to a decade-long effort (1997–2006) around the bicentennial of the American travels (1799–1804), when a series of large-scale Humboldt exhibits and conferences around the globe (Mexico, Cuba, Venezuela, Germany, Colombia, Ecuador, Peru, Spain, England, and Austria) reminded the scientific and general public of the historic and contemporary relevance of one of Europe's most eminent figures of the nineteenth century. These events set the floor for numerous editorial projects (i.e., Humboldt, 1991, 1998, 2004a,b, 2009b,c, 2011, 2012a,b, in press), which were aimed at recovering the original Humboldtian text as a response to a history of reception, in which Humboldt was largely read and commented upon based on highly abbreviated and often poorly translated editions of his works. These new editions have given the international scientific community, mostly in the German-, Spanish-, and English-speaking world, a restored textual ground, an elevated awareness for the impact Humboldt had on his contemporaries, and for the significance his works have for today's readers. The recent acquisition of Humboldt's American Travel Diaries (December 2013) by a consortium of German public and private institutions under the auspices of the Staatsbibliothek zu Berlin (Prussian Cultural Heritage Foundation) will certainly add to this, as it provides an essential element in fully understanding Humboldt's place in the study of scientific practices and travel literature in the nineteenth century.

Abstract

Wilhelm von Humboldt (1767–1835) was a Prussian politician and linguist as well as the founder of political liberalism and the University of Berlin. He founded an anthropological approach to the study of Man, and was also the founder of anthropological comparative linguistics. He studied Basque, Amerindian languages, Kavi, and Austronesian languages.

Wilhelm von Humboldt was a writer, politician, linguist, and language philosopher who developed key concepts in the theory of language and had a strong influence on synchronic and structural descriptive linguistics. He studied at the universities of Frankfurt an der Oder and Göttingen, and maintained lifelong friendships with Goethe and Schiller. He stayed in Paris from 1797 to 1801 and journeyed to Spain and the Basque Country. His subsequent positions included: ambassador to Rome 1802–08, reformer of the Prussian educational system, founder of the University of Berlin 1810, and minister. After resigning from office in 1819, Humboldt carried out linguistic research in Tegel during 1820–35, regularly presenting linguistic papers at the Berlin Academy. He laid down the principles of philosophically oriented anthropological research of the empirical cultural manifestations of humankind. After writing political and esthetic essays, Humboldt concentrated on language. On the basis of Kantian philosophy, he developed a philosophy of language known as the 'formative organ of thought.' He studied many languages, including Basque, Amerindian languages, Sanskrit, Chinese, Japanese, and the Malayo-Polynesian languages to which his major work is devoted. He developed a huge program of descriptive structural linguistics with special emphasis on the 'characterization' of individual languages on the basis of their literature.

Politics

The resignation of Wilhelm von Humboldt, born 22 June 1767 at Potsdam, from his office as the Prussian Minister of Constitutional Affairs at the end of 1819 was a major catastrophe for the political future of Germany. For Humboldt himself it was an act of liberation and a step toward what he regarded as his real vocation, the study of languages, to which he dedicated the rest of his life. Chateaubriand, the French poet and politician, considered this strange scientific activity as the spleen of somebody who had to kill his time as a consequence of the loss of political influence. But it was in fact the achievement of a philosophical and anthropological quest that had started in Humboldt's youth. Studying the languages of the world was not at all something completely extraneous to his political work. The same motivation that would guide his linguistic work had also governed his political activities: it was a quest for the creative center of the human mind and for the achievement of individual felicity and autonomy within the community with other individualities.

This is exactly what had created his political difficulties. At the end of his political career, Humboldt had elaborated a project for the constitutional transformation of Prussia: a proposal to establish a constitutional monarchy with a gradually developing representational system. The French Revolution, which he had welcomed as a decisive step in the history of humanity, had failed in Humboldt's eyes because of its rationalistic one-sidedness: the transformations of France had been governed too radically by abstract rational principles and had not taken into account historically grown entities. For Humboldt, the creation of the new should always be the result of a 'synthesis,' of a sympathetic union of two entities, which, creating a new entity by their union, maintain their identity (the alternative – and lesser – methods of uniting two entities are 'isolation' and 'incorporation,' the former being only the juxtaposition of the two, and the latter, the brutal destruction of their integrity through their unity). Humboldt proposed a 'synthesis' of the traditional prerogatives of the monarch and the interests of the economically active classes (with a consideration also for the traditional rights of the nobility), a 'marriage' that would have transformed Prussia eventually into something new, a constitutional monarchy – and that would have had a model function for the rest of Germany. Not only for the inner organization of Prussia but also for the whole of the area called 'Germany,' Humboldt projected a political structure according to the same principle of a 'synthetical' union: a confederation that would have left quite a lot of autonomy to its members but, nevertheless, would have given important political functions to the whole (like warfare, freedom of movement, and free trade within the union – very much like the United States).

But, in 1819, the times were not propitious anymore for reforms and for the creation of new political structures, as after the defeat of Prussia by Napoleon, which was the beginning of so many happy reforms in Prussia, like the reform of the educational system, the renewal of the municipal administration, and the emancipation of the Jews. Now Napoleon was defeated and the old classes were striking back and were not willing to make any concessions to the bourgeoisie, to the memory of the 'people's war,' or to the experience of freedom and civil rights imported by the Napoleonic armies. Humboldt was the representative of liberal political reforms, and, as such, he had to disappear – in the time of Austria's Metternich, of Hardenberg, and a reactionary king in Prussia.

University and Bildung

But if Humboldt did not succeed in realizing his constitutional dreams, he seems to have had an overwhelming success with the establishment of the University of Berlin some years earlier. Humboldt is best and generally known for this activity, which in fact occupied him for little more than a year (from February 1809 to June 1810) and which was only a part of the reorganization of the whole Prussian educational system. Humboldt indeed made the decisive administrative step for the establishment of the University of Berlin. But what was established was only partially Humboldt's University. He planned the university as a state-independent, economically autonomous institution, with an independence that would guarantee the freedom of research and instruction. Therefore, Humboldt requested that the university should be given a donation of land as the economic basis of that autonomy. Instead, the Berlin University was from the very beginning a state establishment, which – it is true – set unprecedented standards by the quality of its new faculty, by new forms of teaching, and by the unity of research and teaching for professors as well as for students. The concept of the research university was successfully realized. As a state-dependent institution it would forge a well-trained loyal elite for the King of Prussia rather than free citizens of the realm of the spirit.

Humboldt's proposals for the establishment of the Berlin University and the other educational institutions became, however, seminal texts for a pedagogical theory whose central concept was that of *Bildung* (educational and cultural development). Following the convictions of German idealistic philosophy and the classical German poets (Schiller and Goethe), Humboldt wanted human individuals to be given every possible means to develop their physical and intellectual capacities. The educational institutions have to grant access to that formation of the human individual. The main aim of *Bildung* is not the acquisition of professional skills but the unfolding of the highest intellectual and artistic aspirations. Ancient Greece as the absolute summit of human development is the cultural reference of that educational program. The concept of *Bildung* certainly gave an ambitious aim to the educational institutions of Prussia and of Germany as a whole. This concept even served as a justification of otherwise unexplainable investments of the state in intellectual enterprises like the humanities, which have no practical ends. *Bildung* was an enormously successful concept as one of the central values of German identity, giving education a very high position in the value system of the nation. But just as Humboldt's University project was only partially realized in the Prussian University, the idea of *Bildung* – a generous and grandiose idea – did not so much create the (also politically) autonomous and free individuals Humboldt was thinking of, but had more of a compensatory function: consoling the German bourgeoisie for its nonparticipation in political power. Hence, all that wonderful *Bildung* did not prevent the German catastrophe.

Anthropology

The establishment of the University of Berlin and *Bildung* secured Humboldt's place in the pantheon of the German nation. But his main activity and – in the long run – also his most successful intellectual achievement, was his linguistic and philosophical work. In this domain, however, Humboldt is not – as some historiographers tend to think – a founding father of the scientific project of historicocomparative linguistics that is linked to the names of Franz Bopp and Jacob Grimm. Bopp and Grimm invented the principles for a historical reconstruction of the unity of Indo-European, Germanic, Romance, Slavic, and other languages and for the comparison of historically related languages. This was to be the successful – romantic – project of the mainstream linguistics of the nineteenth century. Humboldt is, on the contrary, the founder of an alternative linguistic project, which is more the summary of the linguistic ideas of the Enlightenment: the study of the diversity of the languages of the world. *Verschiedenheit*, or diversity, is the key term of Humboldtian linguistics, which was to flourish – at least in part – in the twentieth century, when the historicocomparative paradigm was relieved by synchronic descriptive linguistics.

Humboldt's linguistic project was integrated into a larger 'anthropological' project. 'Anthropology' in the eighteenth century was a term that designated the empirical study of human beings, as opposed to philosophy, which investigates the universal nature of the human race. Humboldt sketched a vast research program for the investigation of the cultural manifestations of humankind. Understanding the creativity of the human mind was the philosophical motive that gave Humboldt's anthropological project its special dynamics. Two events that occurred in his lifetime were decisive for this research into creativity: first, as for any young intellectual of his generation, was the French Revolution, the creation of a completely new, enlightened, political organization. Hence, one of his first publications was an article on the first French Constitution (1791) and for his friends he wrote a booklength political treatise 'On the limits of the activity of the state' (1792), which was printed only after his death and which became a founding document of political liberalism. The other revolutionary event in Humboldt's lifetime was Goethe. Here again, what fascinated the young intellectuals was the 'genius,' the mystery of an unprecedented creativity. Humboldt lived in Jena, as a friend of Schiller, in close contact with Goethe. He studied Immanuel Kant, whose philosophy was to become the framework of his own theoretical developments. Humboldt's work is centered on the Kantian concept of imagination, *Einbildungskraft*, the faculty of the human mind that is responsible for the creation of the new.

Since imagination as the mediation between the senses and the intellect had remained rather mysterious in Kant's philosophy, Humboldt set out to find its roots. He discovered them in the difference between the sexes. The opposition of the male and the female in nature is the very basis of every new creation, not only of physical generation (*Erzeugung*) but also of the most 'sublime creature' of the imagination: thought. The loving embrace of the female and the male generates new living beings in the physical as well as in the intellectual world. Kant was shocked by Humboldt's somewhat pre-Freudian interpretation of his philosophy. But despite Kant's criticism, sexual union, 'matrimony' (*Vermählung*), and love would be the structural model for everything Humboldt set out to investigate: art, politics, education, and language. Just as dialectics is the

fundamental figure of thought in Hegel, the erotic encounter is the basic structure of Humboldt's thought.

After his reflections on the anthropological roots of creativity, Humboldt wrote a book on Goethe (1798), which contains a very modern theory of esthetics: art is not only a creation of the artist's imagination but also a (languagelike) communicative event between the producer of the work of art and the observers, the readers, the listeners who recreate the work of art in their act of reception and thereby accomplish the creative process.

Language

While still in Jena, Humboldt wrote his first reflections on language: 'On thinking and speaking' (1795–96), a short sketch that already contained the main features of his language theory. Humboldt's sojourn in France and in Spain (1797–1801) would be decisive for his making language the very center of his intellectual endeavors. In Paris, he discussed philosophical issues with the *Idéologues*, in whose philosophy language played a crucial role, and here and in his journey to the Basque Country, he encountered the Basque language whose profoundly divergent structural properties intrigued Humboldt. Later, his brother Alexander would bring linguistic material from America, and in Rome, Humboldt had access to the linguistic materials of the Jesuits (Lorenzo Hervás). For years, the Amerindian languages were Humboldt's empirical linguistic objects before he turned to the Malayo-Polynesian languages to which his main – posthumous – work *On the Kavi Language on the Island of Java* (1836–39) is devoted. The introductory volume of that book, *The Diversity of the Human Language-Structure*, completed before his death on 8 April 1835 in Tegel (near Berlin), is Humboldt's major work. With language, Humboldt arrived at the very heart of his general quest for the creation of the new by that mysterious Kantian faculty of *Einbildungskraft*.

Language is not just a means for the communication of thought; it is the very creation of thought. According to the Kantian system, the senses and the intellect create the concept through their synthesis. But for Humboldt, the concept is not created independently of the word: word and concept form an indissoluble synthetic unity; thought is created as sound. Language is the 'formative organ of thought' ('*das bildende Organ des Gedanken*,' 1903–36: VII, p. 53), 'labor of the mind' ('*Arbeit des Geistes*,' 1903–36: VII, p. 46). Like art, language (thought sound) also needs the dimension of the other: it must be heard and understood. Language as a cognitive activity reckons with the other, language is thought in the dimension of the other: *Mitdenken*, or cocognition. But surpassing art, language is a reciprocal creative activity: the hearer becomes the speaker, 'the word formed by me resounds from the mouth of the other' (1903–36: VII, p. 56). This ultimate reciprocity is the completion of the linguistic syntheses. The duality of I and thou is the 'fundamental type' of language.

Humboldt discovered that language is actually at the center of the Kantian system. Humboldt's language philosophy was a linguistic turn of transcendental philosophy. Since Bacon's discovery of the *idola fori*, European philosophy had become gradually aware of the fact that language is not just a device for the communication of thought but first and foremost a cognitive activity. This insight finds a coherent post-Kantian formulation in Humboldt.

The second important moment of that philosophy of language is the insight that the formation of thought, the linguistic 'transformation of the world into the property of the mind' (1903–36: IV, p. 420), always proceeds according to the special ways of historically particular communities, that is, according to particular languages. There is no such thing as language in general, language comes in languages. Thought generated by language, hence, is not uniform and universal but historically and culturally fragmented in different 'worldviews' (*Weltansichten*). The task of language, the generation of thought, is universal, but that task is realized in thousands of different ways in the different languages of humankind.

Now the new – or Leibnizian – moment of that insight is its positive interpretation: from Bacon onward, philosophy has lamented over the particularity of worldviews in the different languages and wanted to get rid of those 'prejudices'; the semantics of natural languages is like 'a mist before our eyes' (Locke) that philosophical enlightenment must discard. Only Leibniz gave an optimistic twist to the discovery of the linguistically generated diversity of thought when he envisaged a study of all the languages of the world in order to know the 'marvelous variety of the operations of our mind.' Herder took that idea from Leibniz, and Humboldt not only integrated it into the Kantian framework but also developed a huge program of descriptive linguistics.

Comparative Study of Languages

All the languages of the world were to be described according to what Humboldt calls their 'inner coherence' (*innerer Zusammenhang*), their particular structure. The languages of the world had mostly been grasped according to the traditional categories of Greek and Latin grammar. But the structural properties of a language can only be captured through its own categories. Humboldt envisaged an encyclopedia of the languages of the world, a new *Mithridates*. He started a whole series of descriptive works on different languages of the world of which the *Mexican Grammar*, the *Mexican Dictionary*, as well as the *Meso-*, *South-* and *North-American Grammars* (Humboldt, 1994, 2000, 2009, 2011, 2013) have been published recently. A second kind of structural studies aimed at a revised form of general grammar (which was also based on the Greco-Latin grammar): comparative investigations of linguistic categories throughout the languages of the world. Humboldt's article on the dual (1827) is an example of that research. After the completion of these structural descriptions, research into the parental relationships of languages (genealogy) or into structural similarities among languages (typology, classification) can be undertaken.

What is often considered as Humboldt's main contribution to linguistics, the so-called Humboldtian 'typology,' is neither central to his linguistic aims nor did Humboldt propose typology as an alternative to the dominant linguistic school, that is, to the historicocomparative studies of languages. On the contrary, in his last book, his unfinished work on Kavi, Humboldt eventually envisaged a comparative study of the

Malayo-Polynesian languages, which would follow Grimm and Bopp's work on the Germanic and Indo-European languages. Humboldtian typology is a linguistic myth created by superficial readings of his texts. Humboldt was very skeptical about the classifications of the Schlegels, and he explicitly refuted the legitimation of classifying languages, since languages are individuals and should be described as such.

The summit or keystone of Humboldtian linguistics is therefore the investigation of the 'character' of languages. This is just the opposite of classification and typology, of grouping similar entities together. It is a tentative attempt to grasp the very individuality of each individual language. Humboldt was not sure whether 'characterization' was still a scientific task. But whatever it is, it has to be tackled since it is the ultimate aim of linguistics to see how the human mind uses the instruments it has created, to investigate the very end of language: speech and discourse. The – necessary – structural description of a language is only 'comparable to its dead skeleton' (1903–36: VI, p. 147), the life of a language is discourse (*verbundene Rede*), a life giving 'character' to that language. Therefore, only languages that have a multifaceted literature yield the possibility of being described as having characters.

Nearly two centuries after Humboldt's sketch of a huge linguistic program, it can be said that the structural description of human languages he envisaged was the main task and achievement of linguistics in the twentieth century. It is not by chance that Humboldt is present in the seminal theoreticians of modern linguistics (Saussure (*see* Saussure, Ferdinand de (1857–1913)), Bloomfield (*see* Bloomfield, Leonard (1887–1949)), and Hjelmslev). The nineteenth century was not very Humboldtian, with its emphasis on diachronical research as well as in its naturalistic research methods. Humboldt's 'keystone' of linguistics, the 'characterization' of languages, was attempted by some literary-minded linguists (e.g., Vossler), but was discredited by nationalistic and ideological interpretations of linguistic structures. Since the structural descriptions of the languages of the world have now virtually been completed, it is not astonishing that in actual linguistics typological attempts are again very important. The so-called Humboldtian typology is often quoted in that context. But it is – even more than the other famous Humboldtian invention, 'Humboldt's University' – rather a myth than a creature of the author. Without any foundation in Humboldt's work is also the widespread conviction that Humboldt discovered fundamental principles of Chomskyan linguistics, like the 'infinite use of finite means.' Humboldtian linguistics as a whole is in direct opposition to that kind of linguistic research: it is a hermeneutical research into the cultural diversity of human languages in historical communities, preferentially through (literary) discourse, and not a naturalistic investigation of the structure of the universal human mind considered as a universal grammar.

Abstract

Leopold Ranke is counted along with Johann Gustav Droysen (1808–1884), Barthold Georg Neibuhr (1776–1831) and Theodor Mommsen (1817–1903) as one of the most important founders of modern history in Germany and as the most influential international representative of classical German historism. His own research work and his teaching at the University of Berlin made an essential contribution to the circulation and final establishment of modern source criticism. He pushed ahead the autonomization of history as a science, by distancing himself both from the rhetorical tradition of history as an 'art,' and also from the contemporary historical philosophy, particularly that of Georg Wilhelm Friedrich Hegel. With his systematic work from sources he emphasized the importance of empiricism, and simultaneously made it repeatedly clear in theoretical comments and in his historical practice that the individual event or fact can only be interpreted in its surrounding context. His art of portrayal was essential to his success and to his, at times world recognition in the developing modern international field of history, with which style he has gone down in history as one of the founders of modern historiography.

Leopold Ranke was born in Wiehe an der Unstrut in Thuringia on the December 20, 1795 as the son of the lawyer Gottlob Israel Ranke. His family had long served as evangelical pastors in the area of Saxony between the rivers Saale and Unstrut. From 1809 to 1814 he attended the renowned Pforta school at Naumburg in Saxony, and from the spring of 1814 to the summer of 1818 he studied theology and classical literature in Leipzig. He completed his doctorate in 1817 with a (lost) dissertation on Thukydides. In 1818 Ranke started teaching history at the Fridericianum Gymnasium in Frankfurt an der Oder. In 1825 he was appointed associate professor of history at the University of Berlin, and in 1834 he was promoted to a full professor. In 1841 he was appointed official historian to the Prussian state by Friedrich Wilhelm IV, and in 1854 to the renewed parliament. Ranke was ennobled in 1865, becoming Leopold von Ranke, and in 1867 he was named chancellor of the order *pour le merité*. He rejected countless offers to teach at other universities, at Munich among others, and remained in Bérlin, where he died on the May 23, 1886. From 1880 onwards he was almost blind, and was forced to dictate his later works to assistants.

Ranke's career as a historian was influenced less by the historical science of the time, but rather by his interest in classical literature. His earliest existing studies are on the subject of translation and interpretation of classical Greek texts. Recent research has shown that the German literature of his time, Goethe, Schiller, and Friedrich Schlegel, also had an important influence on his conception of historical writing. It is also known that Ranke admired the literary form of contemporary British and French historiography. Ranke's early years were during the era of French hegemony over Germany and Europe, and the time of the rising German nationalist movement from 1806 onwards. These experiences of contemporary history left lasting impressions on Ranke's thinking. His political sympathies lay with Prussian state conservatism. On behalf of the Prussian government, but with independent control, Ranke published the *Historischpolitische Zeitschrift* from 1832 to 1836, through which the government aimed to exert a moderate conservative influence on the public. Ranke had to give up the journal after a short time because of lack of success; however, he did use the opportunity to publish a number of historical-political essays, in which he developed important methodological principles, and also began to sketch out his later, larger works. The most important of these articles are for example *Über die Zeit Ferdinands I. und Maximilians II.* (On the Time of Ferdinand I. and Maximilian II.), *Frankreich und Deutschland* (France and Germany), *Vom Einfluß der Theorie* (On the Influence of Theory) (all 1832), *Rom 1815–1823* (Rome from 1815 to 1823), *Die großen Mächte* (*The Great Powers*) (both 1833), and *Das politische Gespräch* (*The Political Conversation*) (1836). Ranke placed importance on his good relations with the Prussian court, but was also held in high esteem by the Bavarian King Maximilian II, who had attended his lectures as a student at the University of Berlin, and for whom Ranke held a series of free lectures in Berchtesgaden in the September and October 1854 which were taken down in shorthand. The king had wished for 'a short and condensed overview of the motivating ideas of the various centuries of history from the Christian era on,' and Ranke developed basic characteristics of his historical perception in eight lectures which were then published in 1888 under the title *Über die Epochen der neueren Geschichte* (On the Epochs of Recent History).

Ranke's works total 63 volumes, including nine volumes of a world history which he dictated late in his life but was unable to complete. His first work *Geschichte der romanischen und germanischen Völker von 1494–1514* (History of the Latin and Teutonic Nations from 1494 to 1514) (1824) was a great success. It already showed some of the basic characteristics of his conception of Europe, and was of historiographical importance particularly because Ranke made an exemplary critical analysis of his sources in a separate volume, *Zur Kritik neuerer Geschichtsschreiber* (On the Critical Methods of Recent Historians). In this work he raised the method of textual criticism used in the late eighteenth century, particularly in classical philology to the standard method of scientific historical writing. In 1827 he visited the archives of Vienna, Venice, Rome, and Florence and various German libraries with a stipend of the Prussian government and discovered the since

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61133-9

famous Venetian relations, legation reports from the sixteenth and seventeenth centuries, which became an important basic source for the series of his great historical works beginning in 1832. The experiences of the July Revolution in France in 1830 led him to interpret the modern history of the European states more strongly in perspective of the relation between the present and the past. From 1832 to 1836 he published the three volumes of *Die römischen Päpste, ihre Kirche und ihr Staat im 16 und 17. Jahrhundert* (Ecclesiastical and Political History of the Popes during the 16th and 17th Centuries), and from 1839 to 1847 the six volumes of *Die deutsche Geschichte im Zeitälter der Reformation* (History of the Reformation in Germany). These two works were developed in a single process and complement one another. Further main works followed in 1847–1848, *Preußische Geschichte* (History of Prussia), 1852–1861, *Französische Geschichte* (History of France), and 1859–1868, *Englische Geschichte* (History of England), as well as the incompleted world history of 1881–1888. After the foundation of the German Reich in 1870 and 1871, Ranke partly revised his *Preußische Geschichte* by emphasizing the 'German' role of Prussia in the old Reich more strongly in a second edition. Numerous studies concentrating for the most part on Prussian and Austrian history complete his work. It must be noted that the focal point of these works, with editions and investigations on the Prussian state chancellor von Hardenberg and on Friedrich Wilhelm IV, was in the area of contemporary history.

From 1830 onwards Ranke's thought centers on the history of the European states of the sixteenth and seventeenth centuries, based on his experiences of the time. However, depending on his estimation of the problems and their continuations, he did look back into the late and even the early middle ages, and on the other hand pursued the configurations of the European states not only up to 1789–1795, but also into the beginning of the nineteenth century. We can see from the focal point of the sixteenth and seventeenth centuries, the age of the secularized Renaissance papacy, the reformation and religious wars, the modern process of building states and the crystallization of the European powers system and its functioning between repeated hegemonic claims and equilibrium, that Ranke viewed the European historical process as essentially grounded in the tension between state and religion. The state and the church are buttresses of the system, at the same time however also buttresses of change, as they tend to broaden and reinforce their power so widely that they cause opposition and opposite tendencies, just as do the acting personalities themselves. In Ranke's historical perception however, each state and church, as well as their representatives, have a specific 'task,' with which they contribute to the overall human task of cultural development. The task of historians is to recognise this 'task' and the 'leading ideas,' and to portray at which points the protagonists deviate from them, causing turbulences and even historical catastrophes, and where they return to realizing these leading ideas and thereby to a harmonious equilibrium of the forces. Multiplicity is essential for the workings of this self- regulating system of states and religion, or churches. 'States are "Thoughts of God"' (*Politisches Gespräch*, ed. U. Muhlack, p. 95), and historical research pursues their development over the centuries. Ranke's great historical writings begin at the point when the medieval universalism of the church and the 'Sacrum Imperium' of the Germans started to break down and the specific European culture developed, in which the pretention of religious or state universality repeatedly appeared, but was crushed by the resistance of the state and national individualities. Multiplicity and unity are connected in this history of the great European nations and their summing together in the European powers system in such a way as to enable human energies to be realized more productively than ever before.

The recognition of this historical process has for Ranke, a value in itself. Ranke formulated this thought, which is a plea against liberal progressive thinking, repeatedly; most markedly in the sentence from the lectures '*Über die Epochen der neueren Geschichte*': 'Each age is immediate to God, and its value is not based on that which it brings forth, but in its own existence, in its own self, which however does not rule out that something else emerged from it' (von Ranke et al. 1971, p. 60). Ranke hereby opposes every functionalization of historical events and situations for contemporary interests, yet makes it clear that the present cannot be understood without the historical process and that contemporary action may not ignore the way things have come to pass. For example one can learn from the past that is not possible to re-establish the absolute monarchy or the old importance of the church in the 'Age of Revolution.' Therefore Ranke did not limit himself to a purely contemplative ideal of historical insight beyond all practical applications. In his inaugural lecture in Berlin in 1836, '*Über die Verwandtschaft und den Unterschied der Historie und der Politik*' (On the Relation and the Difference of History and Politics), he declared that an insight into the past as free from prejudice as possible, was a condition for the possibility of reasonable politics in the present. Historical insight explains the conditions under which contemporaries act. However, these must be drawn into the leading ideas of their predecessors, and may not criticize them from the standpoint of their contemporary interests. Ranke also described this concept of historical objectivity in various works, the most well known of which being the formulation: 'We have given history the task of judging the past, of teaching the world for the use of future years: the present attempt does not forbid itself such high tasks: it merely aims to show how it really was' (SW 33, VII).

Ranke founded his ideal of objectivity for the most part on historical theology, not on logical insights. The basis of historical insight was for him a certain knowledge of God: 'History is religion' ... 'At least there is the closest connection between them' (letter to Georg Waitz, December 30, 1841, Briefwerk 313). As Ranke saw God as manifested in all historical appearances, and especially in their inner relations to one another, historical insight represented for him the specific modern and up to date search for the recognition of God. The religious conviction that all historical action is carried by providence meant on one hand a limitation of the possibilities of insight, because the historian can at best guess at God's will. On the other hand this conviction lends Ranke's historical perception a harmonistical character, which has earned sharp criticism in the past decades of historism-critical historical science. His ideal of objectivism was rejected by his Berlin colleague and methodological opponent Johann Gustav Droysen but also by his pupil Heinrich von Sybel and by Heinrich von Treitschke, the protagonist of the politically

active, Prussia-oriented liberal-conservative historiography in late nineteenth century Germany.

In the field of German history of the late nineteenth and early twentieth century, however, Ranke was very highly respected. His rather too uncritical successors unfortunately produced a perception of history which did not take sufficient account of the specific forces of the modern age. As mentioned previously, Ranke himself had always related history to the present and had included the French Revolution as well as the reestablishment of the European system of powers at the Congress of Vienna in his continuity-oriented thinking. He saw in the French Revolution in particular, a dynamic element which gave the stagnating European powers system new energies and ability to integrate, so that European state system could regenerate and reinforce itself through increased nationalization. There was no longer room for industrialization, the modern competitive economy and capitalism, liberalism, even socialism and communism in this historical perception.

Leopold Ranke is counted along with Johann Gustav Droysen (1808–1884), Barthold Georg Neibuhr (1776–1831), and Theodor Mommsen (1817–1903) as one of the most important founders of modern history in Germany and as the most influential international representative of classical German historism. His own research work and his teaching at the University of Berlin made an essential contribution to the circulation and final establishment of modern source of criticism. He pushed ahead the autonomization of history as a science, by distancing himself both from the rhetorical tradition of history as an 'art,' and also from the contemporary historical philosophy, particularly that of Georg Wilhelm Friedrich Hegel. With his systematic work from sources he emphasized the importance of empiricism, and simultaneously made it repeatedly clear in theoretical comments and in his historical practice than the individual event or fact can only be interpreted in its surrounding context. His art of portrayal was essential to his success and to his, at times, world recognition in the developing modern international field of history, with which style he has gone down in history as one of the founders of modern historiography. Ranke expressly aimed to make history into a 'pleasure.' His mastery of specifically narrative forms contributed to bridging the gap between the empirical and specialized historian and the bourgeois readership of the nineteenth century. As mentioned previously, one consequences of this esthetization could also be a harmonizing view of events and situations. However, Ranke's narrative mastership did allow him to lead from the apparently coincidental individual event on to the contemplation of the most general insights, in a way that is very plausible for the historical-political consciousness of the nineteenth century. His stories deal with the responsibility of individuals for their fate, without suggesting that they could control this fate. That is the meaning of the sentence, that the historian is to deal with humanity, 'as it is, explainable or unexplainable: the life of the individual, the generations, the peoples, at times the hand of God above them' (SW 33/34, VIII).

Voting and Direct Democracy

Lawrence LeDuc, University of Toronto, Toronto, ON, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In some jurisdictions, citizens have the opportunity to cast a vote on issues rather than only for political parties or candidates. This article considers the factors that shape voting behavior in a referendum or other type of direct vote on issues, examining participation, voter decision making, and the implications of direct issue votes for the health of democracy more generally. The various forms and institutions of direct democracy are considered, as well as the dynamics of initiative and referendum campaigns, the sources of campaign information, and the impact of information and predispositions on opinion formation and voting decisions. Four models of voter decision making are examined, and their relative utility in explaining the outcome of direct issue votes is evaluated.

In some jurisdictions, citizens have the opportunity to cast a vote on issues rather than only for political parties or candidates. In this article, we consider the factors that shape voting behavior in a referendum or other type of direct vote on issues. How do voters make decisions in such circumstances? Do they participate in issue votes at the same rates as in regular elections? What are the main characteristics of initiative and referendum campaigns? And what are the implications of direct democracy for the health of democracy more generally?

Structure and Context

Not all countries practice direct democracy and in those that do it can take on different forms. Initiatives undertaken directly by citizens and referendums called by a government are the two principal institutional models, but there are many variations in these, both in the specific legal requirements and in the frequency of their use.

Varying Forms and Institutions of Direct Democracy

The usage of referendums and initiatives has increased dramatically around the world, both in the number of countries employing such devices and in the number of issues being put to a direct vote in some form (International IDEA, 2008; Altman, 2011; Qvortrup, 2014). There are some established democracies (e.g., Switzerland, Ireland, Italy, Uruguay) in which the institutions and processes of direct democracy are widely used and others in which referendums are employed only occasionally to allow citizens to express their views directly on an important political issue or for more specific purposes such as constitutional amendments or the ratification of international treaties.

Direct democracy comes in many forms, and the issues that arise under different institutional rules and processes are not always the same. A referendum is sometimes mandated by law in countries or states where constitutional amendments require a popular vote, or it may be called by a government or legislature that seeks to test public support for a proposal. Citizen initiatives, on the other hand, are brought forward by members of the public without the sanction of the government. In New Zealand, a nonbinding vote of the people on any issue may be triggered either by citizen initiative or by the government for consultative purposes. Italy employs the *abrogative* referendum or popular veto, in which citizens may force a binding public vote on a law which has already been adopted by the legislature. In many cases, more than one route to a popular vote is possible. Switzerland, one of the countries with the greatest experience in the practice of direct democracy, does not use consultative referendums initiated by the government, but several other types of initiative processes and mandatory constitutional referendums are found there.

In recent years, there have been a number of important referendums in European countries dealing with membership in the European Union or with changes in major European treaties. The rejection by voters in France and The Netherlands of a proposed European Constitutional Treaty ended an attempt in 2005 to create a new constitutional framework for the European Union. Some of the proposals contained in that document were later adopted by the EU member countries in the form of the Lisbon Treaty in 2009, but only Ireland, where approval by the public in a referendum is required by the constitution, held a direct vote on that treaty. There are also newer democracies in which a referendum is often the preferred device for obtaining public approval of a new constitution or for legitimizing a process of fundamental political change such as secession or the restructuring of state institutions. Referendums preceded the declaration of independence of East Timor from Indonesia in 1999 and of South Sudan from Sudan in 2011.

Although there has never been a national referendum on any issue in the United States, the use of direct democracy is widespread in that country at the state and local level. All U.S. states except Delaware provide for amendments to their state constitutions to be submitted to a popular vote, and most states have some type of procedure for putting an issue to a referendum of the people (Cronin, 1989). Twenty-four states have provision for citizen initiatives, in which a group of citizens, upon obtaining a specified number of signatures, may be able to place an issue on the ballot. 'Ballot propositions,' as they are generally called in the U.S., have thus become an

important component of American democracy. In the November 2012 presidential election, there were 174 ballot propositions to be decided in 38 states, including proposals for the legalization of marijuana which were approved by voters in Colorado and Washington and same-sex marriage in Maine, Maryland, and Washington.

How and When Do Initiatives and Referendums Occur?

Governments call referendums for different reasons. In a few cases, such as the referendums that have taken place in Ireland on European treaties such as Nice (2001, 2002) or Lisbon (2008, 2009), the referendums were constitutionally mandated. The same was true of the 1999 Australian referendum on the monarchy, as all constitutional amendments in Australia must be submitted to a national vote. In the case of the Danish (2000) and Swedish (2003) referendums on the Euro, they were *politically* necessary, since the governments in those countries could not have risked adopting the Euro without a public consultation. Similarly, none of the governments of the Nordic countries in 1994 were willing to undertake the historic decision to join the European Union without a referendum (Jenssen et al., 1998). A variety of political calculations often enter into a government's decision to call a referendum on a particular issue (LeDuc and Svensson, 2002). The 1997 Scottish and Welsh devolution referendums, together with a 1998 referendum on local government in London, were in effect all part of the Blair government's wider agenda of institutional reform, but none of these were *legally* required.

Sometimes, the political decisions involved in calling a referendum are part of an electoral strategy. In Quebec, the leadership of the Parti Québécois made a calculation in the course of devising its 1976 election campaign strategy that the commitment to conduct a referendum on the issue of Quebec sovereignty would allow it to decouple the sovereignty question from other election issues, thereby placing it in a more competitive electoral position (Pammett and LeDuc, 2001; Clarke et al., 2004). The party's subsequent victory in the election justified that strategy, but left it with the commitment to hold such a referendum later, which took place in 1980. A second Quebec referendum in 1995 has now made it all but impossible that Quebec sovereignty could ever be achieved without resorting to a third referendum. A similar situation exists in Norway. Having voted twice (1972, 1994) against European Union membership, no Norwegian government would now consider joining the EU without a positive referendum vote.

Government-initiated referendums also frequently take place because a governing party finds itself divided on an important issue. The 1986 referendum in Spain on NATO membership came about for this reason. Similarly, the decision of the Swedish government to hold a referendum on nuclear energy policy in 1980 was taken because all of the major political parties preferred to avoid dealing with that contentious issue in an election campaign, and also because the governing Social Democrats were deeply divided on the issue (Gramberg and Holmberg, 1988). Referendums that come about in this way present a different context for voters than those that arise out of legal necessity or that are part of a partisan political agenda. Partisan cues, which are so important to the voting decision in ordinary elections, may be entirely absent in such situations, or voters may receive mixed messages from well-known partisan political actors (Higley and McAllister, 2002).

Campaigns and Direct Democracy

Earlier literature on direct democracy gave little attention to referendum and initiative campaigns, focusing instead on the institutional rules and norms of direct democracy and on its possible consequences for parliamentary governance and the protection of minority rights. But more recently, the effects of the campaign in providing information to voters on sometimes complex issues and the role of resources and media in affecting outcomes have received greater attention. Referendum and initiative campaigns are *real* campaigns, in which political actors seek to win votes rather than to merely carry on the debate of an issue.

Direct Democracy and Elections

In many instances, a referendum or initiative vote takes place at the same time as an election, usually a regular election for legislative or presidential candidates or other public officials. The practice of holding an election and referendum or initiative vote concurrently is frequently defended on the grounds of minimizing administrative costs, as well as maximizing voter turnout. But one significant disadvantage of this practice is that the referendum or initiative issue may become submerged in the election campaign. On American ballots, propositions do not always receive as much attention as the campaigns for elective offices. Switzerland does not hold referendums to coincide with elections, instead scheduling direct votes on issue proposals three or four times a year, each one typically involving two to five questions.

On balance, the quality of deliberation of an issue is probably better served when debate on an issue does *not* become caught up in the politics of an election campaign. But the risk of holding a separate vote on a single issue is that of lower turnout or voter indifference. This was never a problem with either of the two Quebec referendums, both of which drew significantly higher turnout than the most nearly comparable provincial or federal elections. Neither was it a problem with most of the votes on EU membership that have taken place in recent years or with Australian referendums, in which voting is compulsory. But, low turnout and general voter disinterest in some Irish referendums has not infrequently been a problem in that country, and has sometimes led to the holding of a second referendum on the same issue.

Question Wording

The choice presented to voters in a referendum is typically to vote either YES or NO on a specific question that appears on the ballot. In some instances, the question will be relatively clear and straightforward, as in the 2014 Scottish referendum ("Should Scotland be an independent country?") or the 1994 Norwegian referendum ("Should Norway become a member of the European Union?"). When a governing party has the

opportunity to write the question, it often does so with its own political objectives in mind. The questions in both Quebec sovereignty referendums were written by a government actively seeking a YES vote, incorporating in the wording appealing concepts such as a 'new political and economic partnership' (1995) or the 'equality of nations' (1980). The question used in the 1986 Spanish referendum on NATO membership sought approval under 'the terms set down by the government' but did not specify what those terms were. This facilitated mobilization of supporters of the governing party, many of whom had previously opposed NATO membership. It also enabled the government to structure the debate more around the *terms* that it sought to impose on continued Spanish membership in NATO rather than on the fact of membership itself, a campaign strategy that ultimately proved successful.

The question used in the 1999 Australian referendum on abolishing the monarchy presented a difficult choice to voters because it prominently raised *two* issues – the abolition of the monarchy and the method of election of a new president. In the campaign, it became clear that many voters who favored abolition of the monarchy were also opposed to the provision of the proposal that allowed parliament to elect the president. The Irish referendums on the Nice treaty suffered from a similar problem, in part because the actual question wording in Irish referendums is often technical and legalistic. The question asked voters to "permit the state to ratify the Treaty of Nice and certain related Acts," but said nothing about the specific provisions of those documents. American state ballot propositions often suffer from problems of clarity due to highly technical language or multiple items contained in a proposal. Not infrequently, question wording can be manipulated in various ways to present a different type of choice on the same issue. In Maine, voters in 2012 were presented with a proposal to "allow the state to issue marriage licenses to same-sex couples" while in Minnesota the proposed constitutional amendment stated that "only a union of one man and one woman shall be valid or recognized as a marriage in Minnesota."

Sources of Information

Surveys taken in the aftermath of a referendum campaign regularly show that 'insufficient information' is one of the most common complaints of citizens about the referendum process.

When an issue is partisan, information is likely to flow to voters through the political parties. In the case of citizens' initiatives, which are often undertaken by groups or organizations formed for the purpose, these may become the primary sources of information for voters. Particularly in circumstances such as the European treaty referendums or approval of constitutional amendments, where large and complex packages of proposals are put to a vote, information becomes critical. A similar problem often occurs in the case of U.S. ballot propositions, where complex proposals combined with highly biased sources of information can easily overwhelm voters.

In some jurisdictions, this problem is addressed by having neutral authorities provide 'balanced' information. In Ireland, for example, an independent referendum commission is charged with the responsibility of disseminating unbiased information to the public through its own publications, and of promoting debate and discussion of the issue(s) over the course of the campaign. In California, the Secretary of State is legally responsible for publishing a *Voter Information Guide*, which contains information regarding every proposition on the ballot. Included in the booklet is a summary of the proposal, a statement by the Legislative Analyst regarding its meaning and consequences, and unedited statements by groups supporting and opposing the proposition.

Campaign Regulation

Initiative campaigns in some U.S. states are sometimes criticized as unfair because of the disproportionate amounts of money spent by one side or the other (Sabato et al., 2001). An individual, group, or organization that has been able to bear the high costs of qualifying a proposal for the ballot is often able to spend far more money in a campaign to secure its passage than opponents are able to raise to defeat it. Similarly, access to the media through which voters obtain information on ballot propositions can be a contentious matter. In countries where some media such as television stations are state controlled, parties or groups on one side of an issue may be able to obtain preferential treatment or greater access. In those jurisdictions where all media are privately owned, those with more resources may hold the advantage.

The answer to difficulties posed by the inequality of resources is sometimes seen in tighter regulation of referendum campaigns. Steps can be taken to assure that the amount of money spent in a campaign falls within defined limits, that campaigners for both sides of an issue have sufficient access to the media, and that voters hear the arguments put forward on both sides of an issue. Subsidies are used in some (primarily European) jurisdictions to level the field. Channeling all activities through officially sanctioned 'umbrella' committees may be another way to assure a more evenly balanced campaign. But such regulations are difficult to formulate and sometimes even more difficult to enforce. Ireland has perhaps the most tightly regulated environment, while other jurisdictions such as Switzerland maintain much lighter regulation of campaign activities and finances.

Participation and Engagement

The levels of participation and engagement of citizens voting on an initiative or referendum proposal are sometimes insufficient to provide a true and accurate reading of public preferences or to give full legitimacy to the result. Voting choices may in some circumstances be based on limited information, or even on misinformation transmitted by the opposing sides in a campaign.

Voter Turnout

Turnout fluctuates more widely in referendums than it does in national elections. In general, it tends to be lower, but can sometimes rise to higher levels when a particular issue engages wide voter interest or an intense campaign is waged by interested groups. When turnout is low, the ability to mobilize one's own supporters counts for more. When it rises, it is

generally because the issue itself is perceived as an important one. Some referendums in which turnout registered higher than that of a comparable national election were the 1994 EU membership referendum in Norway, both Quebec sovereignty referendums, the 1992 Canadian constitutional referendum, and the Danish and Swedish referendums on the Euro. Turnout in both Irish referendums on the Nice treaty was very low in comparison with national elections, and the low turnout of only 35% of voters in the first (2001) referendum was widely blamed for the outcome.

Turnout is also typically low in Swiss initiative and referendum votes, sometimes falling below 40%. But turnout also tends to be low in Swiss elections, and referendum participation is frequently higher than electoral participation, depending on the salience of the particular issue being considered. In the case of a 2005 vote on registration of same-sex partnerships, for example, turnout was a full 11% higher than in the 2003 federal assembly election. Other recent Swiss referendums that have drawn higher rates of participation were a 2004 vote on acquisition of citizenship and a widely publicized 2009 initiative banning the construction of minarets (both 54%).

Turnout is also a serious problem in many of the initiative and referendum votes held in the U.S. states. Typically, such items appear on an electoral ballot together with other public offices. But the turnout then depends largely on the election in which the vote is occurring, and not on the propositions per se. Because turnout in U.S. presidential elections tends to be higher than in off year or state elections, items that appear on a presidential ballot achieve higher levels of participation. But turnout on U.S. ballot propositions must also be measured in terms of the total vote cast on the specific item, rather than as a percentage of those going to the polls, since many voters will fail to vote on some or all of the propositions appearing on the ballot. A 'drop-off' of as much as 10% is fairly typical, but for some propositions it can be much higher.

Some jurisdictions impose a turnout quota on referendum votes in order to assure an adequate level of participation. In Italy, a referendum result is ruled invalid unless 50% of voters participate. The relatively low participation rates in Swiss votes have in general seemed to be less of a problem in that country than in some other instances such as the first Nice referendum in Ireland, where low turnout appears to have directly affected the outcome. Whatever the appropriate level might be, it is clear that turnout is connected directly to legitimacy. A vote in which only a small minority of citizens participate may create circumstances under which the legitimacy of the process itself may come under challenge. But, turnout cannot be considered in isolation. It is affected by many other factors including the timing of votes, party mobilization, levels of information, and the nature of the campaign.

Opinion Formation

Not uncommonly, the issues that are presented to voters on a referendum or initiative ballot are ones with which they are for the most part unfamiliar until they are called upon to make a choice. Voters cannot generally be expected to have well-formed opinions on an issue that has not previously been a subject of any broad public debate. Some referendums particularly fitting such a profile are those that involve complex international treaties, large packages of constitutional provisions, technical matters such as bond issues, or various types of institutional change. The 2011 British referendum on electoral reform presented voters with the opportunity to change the electoral system from First-Past-the-Post to an Alternative Vote (AV) model, but few voters would have been familiar with AV prior to the commencement of the debate. In these circumstances, campaigns based on misinformation or distortion are more likely to succeed. Such referendum campaigns are often highly volatile, and frequently result in the rejection of a proposal by a risk-averse electorate that lacks sufficient information regarding the implications of a proposed change.

By contrast, where an issue is a familiar one in the political arena, or where parties take clearly competing positions, the voting decision is easier and tends to be made earlier in the campaign. Here, opinion is much firmer and less subject to rapid change or sudden reversal. Voters will often have strong cues based on partisanship or ideology, and be receptive to arguments presented by familiar and trusted political leaders. The 1995 Quebec sovereignty referendum is a good example of a campaign in which the PQ government knew that it could count on the nearly universal support of the partisan voters who had brought it to power, but also needed the votes of others in order to secure a majority for its sovereignty proposal. The Danish (2000) and Swedish (2003) referendums on the Euro, an issue which had been debated and discussed extensively in national politics, also provide good examples of this pattern, in which the government believed that it could win the referendum by persuading a relatively small number of undecided voters to support the YES side.

Zaller's (1992) model of opinion formation is particularly well suited to the study of public opinion and voting behavior in referendums. As he argues, any process of opinion formation proceeds from an interaction of *information* and *predisposition*. When strongly held predispositions are merely reinforced by the campaign, referendums begin to take on some of the characteristics of elections, in which factors such as party identification or ideological orientation typically play a crucial role. But when parties are internally divided, ideological alignments are unclear, or an issue is new and unfamiliar, voters might be expected to draw more of their information from the campaign discourse. Under these circumstances, the outcome of the contest is unpredictable and information becomes critical.

Voting Behavior in Referendums

The voting decision in referendums on issues which have been discussed extensively in other political arenas, or in which there are strong linkages to partisanship or ideology follows more conventional models of voting choice and tends to be made earlier in the campaign. In contrast, a context in which there is little partisan, issue, or ideological basis from which voters might tend to form an opinion introduces greater uncertainty. In these settings, other models of voting choice involving 'short-cuts' or 'risk aversion' become more applicable.

Models of Voting Choice

The context in which a referendum or initiative vote occurs and the type of issue on which voters are asked to render a decision will act to shape their decision process. When an issue is strongly connected to existing partisan or ideological cleavages, or when it has been the subject of an ongoing political debate in which the public is engaged, the voting choice will be similar to that found in elections. On an issue such as Quebec sovereignty, for example, we would expect predispositions to be strong and the levels of information to be high. Because the voting decision will be easier in these circumstances, we would expect high levels of engagement and participation and relatively modest movement in sentiment over the course of the campaign, since the opinions of many citizens are already well formed and strongly held.

The opposite is more likely to occur in situations where an issue is new and unfamiliar to voters, parties are divided, or the linkage to other political issues is weak. Predispositions will be low, and information flowing from the campaign may act to shape opinions. Such campaigns tend to be much more volatile, sometimes leaving the outcome in doubt until the votes are counted. Turnout is often lower in such circumstances, owing to voter uncertainty or indifference. Proposals are often rejected by voters under these conditions, in part because of low information and/or risk aversion. The 2011 British referendum on electoral reform displayed many of these characteristics, with a turnout of 42% and a decisive NO vote. In a study of that referendum, Whitely et al. (2012) identified and tested four decision models used by citizens to determine whether to participate and/or how to vote. They labeled these rational choice, cognitive engagement, heuristics, and mobilization. Although the terminology employed sometimes varies, these models of choice will be familiar to scholars studying voting behavior in other countries where direct democratic votes are more commonplace (see, for example, Bowler and Donovan, 1998; Buzzer and Marquis, 2002).

Rational Choice

Students of electoral behavior will be familiar with rational choice models, in which recognized self-interest is hypothesized to drive voting decisions. Voters may be expected to support a proposal if they see a benefit to themselves accruing from its adoption or to vote to reject it if they detect a threat to their interests. But for this model to apply, voters must have sufficient information about a proposal in order to determine its possible benefits or costs. Uncertainty or indifference may lead to abstention, which under this model is also a clearly rational decision. Why participate if the benefit is uncertain or the available information regarding its effects is inconsistent?

Applied to the British example, Liberal Democratic voters or those identifying with other smaller parties might have been expected to support the proposed reform, since the potential benefits to their party were more evident. Labour voters, on the other hand, might have been more indifferent to the proposal, since the potential costs or benefits to their party were much less clear. Further, because levels of information regarding the proposed reform were low, and the campaign contained much misinformation, many citizens could reasonably be expected to abstain. Turnout in the referendum in fact might have been even lower than it was had it not been scheduled concurrently with local and regional elections in many parts of the country.

Cognitive Engagement

A cognitive engagement model bears some similarity to rational choice in that voters require some information and knowledge about a proposal in order to come to a voting decision. On an issue such as electoral reform, engaged and politically knowledgeable citizens are likely to have sufficient information. In the study of the 2011 British referendum, Whitely et al. (2012) found that political knowledge was strongly related to a YES vote. But they also argue that disengagement or lack of knowledge, rather than leading to abstention, was more likely to lead to support of the status quo – in this instance meaning a NO vote on the AV proposal.

There is considerable survey evidence in other studies of referendum voting, particularly on certain types of issues, that a combination of risk aversion and lack of information can easily prompt a NO vote rather than abstention (LeDuc, 2009). Respondents to postelection surveys often give 'lack of information' as their reason for a negative choice. We might add that this dynamic is frequently reinforced by the nature of modern media campaigns (de Vreese, 2007). Attacking a proposal is a common campaign tactic, and opponents of a proposal do not necessarily have to make a coherent case against it. Rather, they can attack it on a number of different fronts, delivering the not so subtle message "when in doubt, vote NO." This strategy was particularly evident in the campaigns against the European Constitutional Treaty (Hobolt, 2005).

Heuristics

In addition to seeking information that will allow them to come to a decision, voters also look for cues – sometimes also referred to as 'short cuts' in the voting behavior literature. As Lupia and McCubbins (1998) put it, citizens learn 'what they need to know' in order to be able to cast a vote on a proposal. In the case of the British AV referendum, the Prime Minister's very public support of the NO side communicated a strong message to Conservative voters. In many initiative and referendum campaigns, opinions will often be shaped by the cues provided by political parties, prominent opinion leaders, or groups and organizations engaged in the campaign. This type of knowledge is often sufficient. Voters do not need to know all of the details of a proposal in order to reach a decision.

An important variation on this theme is found in what are generally called 'second-order effects' (Garry et al., 2006). Decisions may be affected by opinions about the particular individuals or groups involved in a campaign rather than the substance of a proposal. A government that calls a referendum may find that the vote becomes a test of its own (un)popularity rather than a vote on the substance of its proposal. Constitutional initiatives undertaken by unpopular governments often fail, partly for that reason, as did the 1992 Canadian Constitutional package (LeDuc, 2002, 2003). Conversely, a popular leader or a newly elected government may be better positioned to build support for an initiative. The Blair government moved quickly following its election in 1997 to bring forward its devolution and local government reform proposals for submission to a popular vote.

Mobilization

As noted earlier (Section Campaigns and Direct Democracy), initiative and referendum campaigns are *real* campaigns, in which parties or groups seek to win votes rather than merely engage in an issue debate. In the British referendum campaign used as an example here, the two rival campaigns (*Yes to Fairer Votes* and *No to AV*) actively sought to communicate their messages to voters through the media and other sources and to motivate their potential supporters. In a short and intense campaign, particularly on an issue with which citizens are relatively unfamiliar, such activity has an impact both on opinion formation and participation. As in an election campaign, getting one's message across and getting voters to the polls can matter a great deal.

Referendums can differ considerably in levels of mobilization, but resources and organization clearly matter. Whitely et al. (2012) found that this factor was of modest importance in explaining the outcome of the 2011 British electoral reform referendum, at least in comparison with other variables in a multivariate analysis of the vote – perhaps because the outcome of that contest was never really in doubt. But in much closer contests such as the 1995 Quebec sovereignty referendum or the 2000 Danish referendum on the Euro, mobilization, both cognitive and organizational, may be of critical importance in determining the outcome. Conversely, the failure of one side or the other to effectively mobilize its potential supporters can also lead to an unexpected outcome, as in the case of the 2001 Irish referendum on the Nice treaty.

Conclusion

Direct issue votes differ widely in terms of the choices presented to voters and the context in which such votes take place. As the studies cited here demonstrate, the decision processes followed by voters in such contests, although now fairly well known, continue to suggest high levels of uncertainty with respect to the outcome of referendum or initiative votes. Voters follow different paths both to a decision to participate and how to vote. As the study of the 2011 British referendum found, there is some evidence in support of all four models of choice discussed here, even within the context of the same referendum. Not all voters reach their decision of whether and how to vote in exactly the same way. But we would expect that, even in different settings with other choice sets, all four models of choice are likely to have some validity, although the relative weight of these alternative decision processes may vary considerably. Direct democracy continues to gain support around the world, and it remains popular with voters in those jurisdictions that conduct such votes regularly. But, as in elections, voting choice continues to be a subject of continuing interest to both scholars and practitioners of democratic politics. Issue votes, when they occur, are closely intertwined with more traditional forms of electoral politics.

Abstract

The idea of 'class voting' refers to the tendency for citizens in a particular social class to vote for a particular party, political candidate, or groupings of these, rather than an alternative option when compared with voters in another class, or classes. This article overviews past and current comparative research into changes in and explanations of such class-based political behavior and signals its continued significance. Particular emphasis is placed on the implications of choices of method and measurement for estimating the strength of the association between class and vote, and on the importance of developing and testing theories that can account for variation in the strength and form of the class–vote relationship.

The idea of class voting appears straightforward: it refers to the tendency for voters in a particular class to vote for a particular party, political candidate, or groupings of these, rather than an alternative option when compared with voters in another class, or classes. In other words, it describes a pattern of association between class and vote. Yet this simplicity hides considerable intricacy and ambiguity. The definition of social class in and of itself introduces much confusion – class is a much debated, even 'essentially contested,' concept. The issues raised become more complex still when class concepts are translated into measures of class position that allocate voters to classes and when attempts are made to summarize statistically the class–vote association. Explaining patterns of class voting and understanding their implications raises many more unresolved questions. All of these theoretical and methodological issues have at times been the focus of dispute. In addition, however, there has been one major substantive argument that has received more attention than all other questions and which has touched on all of them: has class lost its importance as a source of voters' political preferences?.

Historically, interest in class voting arose in response in part to the failed agenda of Marxism. For classic texts in political sociology electoral politics was an expression of 'the democratic class struggle' (Anderson and Davidson, 1943) that replaced, at least for the short-term, the predicted class-based revolution. This in turn led to a focus on class voting as a dispute between just two classes, the working class and the middle class, and their representatives, parties of the left and right. Early research also relied on data obtained at the level of electoral constituencies. Given the well-known problems with inferring individual vote choices from aggregate data this work had to make strong assumptions about how voters in different classes actually voted. To help overcome this limitation, modern social scientific studies of class voting have focused on its measurement through surveys of voters. From its beginnings in a few national election studies this data base has expanded through time and space to create a large body of evidence on class voting that now informs academic debate.

The Two Class/Two Party Era

The baseline for many current studies was set by Robert Alford's (1967) analysis of trends in class voting in four Anglo-American democracies (Australia, the UK, Canada, and the USA) between 1936 and 1962 using a measure of social and economic position in which occupations were aggregated to form a dichotomous manual/nonmanual class division. He also introduced the most commonly used, cited, and criticized measure of the level of class voting: the 'Alford index.' The Alford index is simply the difference between the percentage of manual workers that voted for left-wing political parties on the one hand and the percentage of nonmanual workers that voted for these parties on the other. This became standard practice in the cross-national and over-time analyses that followed, and which usually concluded that class voting is in decline. Lipset (1981), for example, presented evidence of a downward trend in the UK, Germany, and the USA between 1945 and 1980; while Inglehart (1997) points to evidence of a continuing decline from the early 1980s onwards. Indeed, whether or not class voting in modern industrial societies has declined is, for many commentators, no longer an issue. The question is *why* has it declined? A plethora of explanations have been proposed to account for this outcome (see Goldthorpe, 1996; Manza et al., 1995): some assert that it has lost its importance as a determinant of life-chances and in consequence its role as a source of divergent political interests because the working class has become richer, white-collar workers have been 'proletarianized,' or because of extensive social mobility between classes. Others argue that 'postindustrial' cleavages, such as gender, race, ethnicity, public versus private sector, and various 'identity groups,' are emerging and replacing class-based conflict. Postindustrialism also impacts on class voting through the rise of postmaterial values as a basis of party preference, which has led to the 'new left' drawing its support from the middle classes thus weakening the class basis of left-right divisions; while rising levels of education and 'cognitive mobilization' have supposedly produced voters that are calculative and 'issue oriented' rather than driven by collective identities such as class.

Whatever their strengths and weaknesses – and there are many questions and doubts that remain unresolved in each case – all of these explanations assume that there is indeed a widespread, secular decline in class-based political action which then has to be explained. However, answers to questions about change have been strongly conditioned by choices of method and measurement. The literature on the decline of class

voting that followed Alford's work has been characterized by shortcomings in both these respects.

For example, one problem with the manual/nonmanual distinction is that it obscures variations in the composition of the manual and nonmanual classes. Any changes in their composition may lead to spurious change in estimates of class voting. Thus, if skilled manual workers are more conservative than unskilled workers and the number of skilled workers increases, the difference between manual and nonmanual workers will decline even if the relative political positions of skilled, unskilled, and nonmanual workers remain the same. With this and similar indices the measurement of the class–vote association is open to confounding by changes in the shape of the class structure and in the general popularity of the parties. In other words, this type of index confuses differences in the marginal distributions of the variables with differences in the association it is supposed to measure. The same problem applies to the apparently more sophisticated ordinary least squares regression techniques used in, among others, Franklin, Mackie and Valen's (1992) ambitious 16 nation study that represents, arguably, the culmination of this tradition.

Recent Innovations

In recent years, therefore, the rather atheoretical manual/nonmanual representation of class voting has been to a large degree superseded as researchers have taken into account more nuanced ideas about class structure. Most influential has been the class schema developed by John Goldthorpe and his colleagues (Erikson and Goldthorpe, 1992). First used to study patterns of class voting over time in Britain by Heath *et al.* (1985) this instrument, unlike many other measures of class, has been empirically validated. The main classes identified by the Goldthorpe schema are the petty bourgeoisie (small employers and self-employed), the service class, or salariat (professional and managerial groups), the routine nonmanual class (typically lower grade clerical 'white-collar workers'), and the working class (foremen and technicians, skilled, semi-, and unskilled manual workers). The principal distinction underlying the distinction among the employee classes in the schema is between a service contract in which employees receive not only salaried rewards but also prospective elements – salary increments, job security and pension rights, and, most importantly, well-defined career opportunities – and a labor contract, in which employees supply discrete amounts of labor, under supervision, in return for wages which are calculated on a 'piece' or time basis. As the employment relationship of the service class in relatively advantageous in terms of employment and payment conditions, occupational security, and promotion prospects, its members have a stake in preserving the status quo. In contrast, the disadvantages of the labor contract can explain why the working class provides a basis of support for the redistributive programs of the left.

This shift to greater complexity in the measurement of class has been accompanied by a similar move away from the measurement of political choice as a dichotomy of left versus right (or left versus non-left) to a fuller representation of the voters' spectrum of choice at the ballot box. Apart from its simplicity, the main reason for the use of a dichotomy to represent voter choice seems to have been a desire to make systematic cross-national and over-time comparisons. Unfortunately, the selective nature of what is being compared undermines any true comparability. The problem is analogous to that faced in the analysis of class position. Changes in the composition of composite categories such as 'left' or 'non-left' may lead to spurious changes in estimates of class voting. The use of dichotomies to represent vote choices and social classes also precludes from observation any processes of class–party realignment. The concept of class *re*alignment in voting implies a change in the pattern of association between class and vote without any change in the overall strength of this association – i.e., without class *de*alignment (or, of course, increased alignment). But this cannot be discerned if the distinction between realignment and dealignment is prevented by restricting the numbers of parties and classes to two.

The final innovation of the 1980s and 1990s is in the statistical measurement of the class–vote association, with a move from Alford type indices to ones that are based on odds ratios, which measure the strength of the relationship between class and vote independently of the general popularity of political parties or changes in the sizes of classes. The use of logistic modeling techniques likewise capitalizes on this basic feature of the odds ratio and allows the relationship between more complex class and party systems to be summarized, thus complementing and facilitating greater sophistication in the representation of class and vote.

Research using these advances comes to rather different conclusions than those in the two-class, two-party tradition. Studies in the UK (i.e., Heath *et al.*, 1995) have found little evidence of declining class voting and have concluded that 'trendless fluctuation,' or at most a 'one-off' change, best captures the pattern of association in class voting over time. The USA, by comparison has seen the growth of a new class – vote cleavage – between those who vote and those who do not – as a deficit of working class interest representation that has been associated with increased class differences in participation (Hout *et al.*, 1995). Various studies reported in Evans (1999) show that although there is evidence for a linear decline in left versus non-left class voting (Nieuwbeerta and de Graaf, 1999), it is not typical. For example, when examined over the long-term, levels of class voting in the UK were found to have increased during the 1940s and 1950s before falling back in the 1960s; while the 1990s have seen increased levels of class voting in new post-communist democracies as these societies have undergone the rigors of marketization. Only in certain Scandinavian countries is there robust evidence of a decline from an unusually high degree of class voting to levels similar to those in other Western democracies.

New Directions

The debate on class voting has been strong on evidence and weak on theory. Most scholars have assumed a sociological, relatively deterministic account of the transition to industrial and postindustrial politics, but there are those who have rejected these in favor of more voluntaristic models. Kitschelt (1994), for example, argues that the electoral fortunes of European social democratic parties are largely determined by

their strategic appeals, rather than by secular trends in the class structure – a line of reasoning that echoes Sartori's (1969) influential emphasis on the importance of organization, and especially parties, in the creation of class constituencies. From this perspective there is reason to believe that even in advanced industrial societies class voting might increase as well as decrease. It also implies that the adoption of class-relevant policy programs should be associated with an increase in the class basis of partisanship. Some evidence for this has been presented by Evans *et al.* (1999) who show a relationship over time between left-right polarization in parties' manifestos and the extent of class voting.

This is not to say that sociological changes have no impact, however. Changes in the relative *sizes* of classes have been thought to have implications for party strategy: most importantly, in a change to a 'catch-all' strategy by parties on the left in response to the shrinking class basis of support for those parties (Przeworski and Sprague, 1986). In some political systems such moves leave open the space for left parties to attract support from marginalized working class groups; in others, such as first-past-the-post systems, we might expect that the start-up costs for electorally viable left parties would be too great. Unfortunately, many of these arguments still await rigorous tests using survey analysis. Research that tries to unravel *why* voters in different classes vote differently is in short supply, though Weakliem and Health (1994) provide evidence of the role of rational choice and inherited preferences, while Evans (1993) models the effects for future expected rewards and the likelihood of promotion conditioned by position in the life-cycle. A more explicit link between models of class voting and their dependence on advances in theories of voting behavior more generally is an area where further development might usefully occur.

Abstract

Because democracies choose their governments via the ballot box, the bulk of the literature on voting behavior deals with its decisional component, focusing on who votes and for whom. This article presents a comparative assessment of research on electoral choice and electoral turnout, along with the main theories and empirical findings in the field, from the founding sociological, psychological, and economic postwar models to the recent development in the genetics of politics.

Paradigms Explaining Voting Choice

Electoral geography was the first, and for a long time the only, clue for understanding political behavior, linking voters' choices to the social structures and the religious and political traditions of the places where they lived. Since the earliest studies of André Siegfried or Herbert Tingsten, this contextualized or ecological approach, based on the analysis of aggregate electoral data, has gained in statistical sophistication (for the latest trends see Warf and Leib, 2011). Its limitation lies in the fact that the unit of analysis considered is the group – people living in the same constituency, the same district, the same region, etc. – and that the correlations observed at the aggregate level do not necessarily hold true at the level of the individuals, as Robinson's (1950) famous article on the ecological fallacy reminds us. Opinion polls provide a better tool for understanding individuals' behavior, asking them directly how and why they vote. Since World War II, survey-based research has given a new impetus to electoral sociology, especially in the United States, where the pioneer studies and the classic models explaining vote choice were developed.

The Columbia Model

The sociological model originates from the local surveys conducted by Paul Lazarsfeld and his colleagues at the Bureau for Applied Social Research of the University of Columbia. Repeated interviews with a randomly selected panel of voters, first in the district of Erie County, Ohio, during the 1940 Roosevelt–Wilkie presidential campaign, then in the town of Elmira, New York, at the time of the Truman–Dewey contest, revealed, to their surprise, that the campaign had but a limited effect on voters' choices. Mostly, it reinforced long-standing and diffuse political preferences that reflect the norms of the groups they belong to. Constructing an index of political predisposition based on social class, religion, and rural/urban residence, the authors of *The People's Choice* can predict accurately how people vote. Those combining a rural residence, Protestant affiliation, and high social status tend to support the Republicans, whereas those who are working class, non-Protestant, and residing in urban areas vote mostly for Democrats. The main conclusion of their book is that "A person thinks, politically, as he is, socially. Social characteristics determine political preference" (Lazarsfeld et al., 1944). And this social anchoring accounts for the relative stability of voting choices, except among the cross-pressured or poorly integrated voters. However, in his later empirical and theoretical work such as *Voting* (Berelson et al., 1954), Lazarsfeld was to develop a more complex view of action in general and more particularly of voting behavior. (His research evolution is related in Lautman and Lécuyer, 1998.)

The Michigan Model

Reacting against what they see as a social determinism, Angus Campbell and his colleagues at the Survey Research Center (SRC) at the University of Michigan propose a psychological model focusing on individual decision making. Reconstructing the chain of events that converges in what they call the 'funnel of causality,' they give special attention to the attitudes formed toward candidates, issues, and parties. On the basis of nationwide panel surveys conducted during presidential elections from 1948 to 1956, they state in *The American Voter* (Campbell et al., 1960) that party identification is the key factor orienting vote choice. By that they mean an affective attachment to a specific party, formed early in life, generally passed on from parents to children and reflecting individuals' social and religious backgrounds. It functions as a filter coloring their political perceptions and guiding their votes, especially for the least sophisticated: "Like the automobile buyer who knows nothing of cars except he prefers a given make, the voter who knows simply that he is a Republican or Democrat responds directly to his stable allegiance without the mediating influence of perceptions he has formed on the objects he must choose between" (Campbell et al., 1960). Lazarsfeld portrayed voters as social conformists; the Michigan team sees them more as political believers. Yet their conclusions are very similar: average voters are far from the democratic ideal of rational and active citizens. Most of them are not interested in politics, display low levels of ideological awareness, and are unfamiliar with the candidates and the issues at stake. They vote according to long-standing political preferences shaped by their early socialization.

The Economic Approach

The third approach stems from Downs's seminal essay, *An Economic Theory of Democracy* (1957). It postulates, along the lines of the neoclassic economic paradigm, that voters

 http://dx.doi.org/10.1016/B978-0-08-097086-8.32169-9

are rational and that their choices are based on a cost–benefit calculation. Voters cast their votes for the party or the candidate from which they expect the maximum utility, or benefits. The electoral decision between party A in office and opposition party B boils down to a simple equation: the difference between the benefits expected from the victory of party A (Ua) and the benefits expected from party B (Ub). Voters will favor party A if they see the difference between Ua and Ub as positive, party B if the difference is negative, and will not bother to vote if they see no difference. Since Downs's pioneering work, two distinct research fields have developed. The spatial approach of politics has been renewed by directional models (see Merril and Grofman, 1999). Voters won't necessarily choose candidates closer to themselves in a policy space (proximity voting); they might prefer more distant candidates but who are on the same side of an issue as themselves (directional voting), or they might prefer those who could move policy closest to them (discounted proximity). Econometric models, based on the simple idea that voters punish or reward candidates according to the state of the economy, have been sophisticated. Some correlate aggregate electoral results with global economic indicators, such as purchasing power, inflation rates, and unemployment rates. Others use survey data to analyze individual pocket-book voting based on the evaluation of candidates past (retrospective voting) or future performances (prospective voting). Their common goal is to shift attention from the people's characteristics to the supply side of politics, the specific goods offered on the electoral marketplace by competing parties and candidates, in a given election.

The Decline of Cleavage Voting

These three models have been guiding most electoral research agendas.

Class Dealignments

In the wake of the sociological model, attention was first given to the effects of social class and religion, even more so in Europe, where party systems were built historically on the bases of social and religious conflicts and cleavages (see Lipset and Rokkan, 1967). Rose's (1974) classic study of voting patterns in 15 democracies shows that class in Scandinavian countries and religion in the others are by far the most predictive factors explaining postwar electoral behavior, a working-class position predisposing to a left-wing vote and regular church attendance to a right-wing vote. Then, in the 1960s, the Michigan paradigm became the leading model, inspiring nationwide research surveys in Europe (Thomassen, 1994) especially in Britain, where Butler and Stokes (1969) explained long-term alignments of British voters by their party identification, itself rooted in their social backgrounds. What became known as the two-class, two-party model does not fit as well in countries such as France, with its multiparty system. There, Left/Right orientations are the substitute for party identification but are equally rooted in religion and social class (Michelat and Simon, 1977).

Neither model, though, could account for the increasing electoral change that appeared in the United States at the end of the 1960s and in Europe by the end of the 1970s. On the basis of the SRC presidential surveys between 1956 and 1974, the authors of *The Changing American Voter* (Nie et al., 1976) reveal a decline of party ties. The proportion of independent voters, who define themselves as neither Republican nor Democrat, doubled between 1964 and 1974. Among those who still identify themselves with one side or the other, the proportion who declare a strong attachment or have a positive image of a party is declining, and the very link between party preference and voting is weakening. Voters seem more interested in politics, more aware of the issues at stake, and more inclined to choose their candidates according to their political stands, whatever party they belong to.

Parallel studies in Europe detect similar trends of electoral volatility or instability of voting choice (Pedersen, 1979) and partisan dealignment, or gradual moving away from all parties (Crewe and Denver, 1985), which is seen as a structural feature of the emerging postindustrial society. Social and geographical mobility is blurring the traditional class cleavages and loosening community ties. Progress in education and exposure to the media have increased the average levels of political sophistication. The rise of the permissive and individualistic set of values coined as postmaterialist by sociologist Inglehart (*The Silent Revolution*, 1977) encourages a new style of politics, more demanding and protest prone, and promotes new postmaterialist issues – environmental, feminist – that cut through traditional party lines. All these trends converge to make citizens less dependent upon existing parties to make their choices. Voters are seen as being autonomous, strategic, rational, or reasoning, and the developing cognitive sciences enrich studies of political reasoning mechanisms, the way voters process and organize information, the cues they rely on to make decisions, etc. (Sniderman et al., 1991). Short-term issues or candidate-centered voting could well be taking the place of the formerly stable cleavage voting, which had a partisan, religious, or social basis (Franklin et al., 1992).

Class Realignments

But a second research trend has taken an opposite stand, questioning the extent of this dealignment process by casting doubts on the way it is measured. The most heated controversies have developed around the supposed decline of class voting (for a summary, see Evans, 1999). The simplest and most widely used indicator has been Alford's index (1963), which measures the difference between the proportion of manual and nonmanual voters voting for the Left. For instance, if all the British working-class voters supported the Labor party and none in the middle classes supported it in a given election, the value of the Alford index would be 100%, indicating perfect class voting. Measured by this index, the downward trend is undeniable. Class voting in post–World War II elections has decreased, for instance, by almost half in Britain and by more than two-thirds in Germany. But critics underline several weaknesses of such an index. Its dichotomous nature does not take into account the complexity of postindustrial occupational structure or the complexity of party systems. It is statistically

biased because it does not consider the changes in the marginal distributions of the two classes and of the two votes between one election to another. And it measures only dealignment, whereas various processes of electoral realignment along new cleavages, such as private sector vs public sector, self-employed vs wage-earners, or educated vs noneducated voters, seem to be taking place in postindustrial democracies, as shown by multiclass approaches using detailed occupational classifications and sophisticated measures such as odds ratios or log-linear models. If in the long run there is growing evidence of the decline of class voting, it is not linear and differs among countries. In Britain, for instance, from the 1960s to the early 1990s Heath et al. (1991), contrary to previous findings, found no decline in class voting, just 'fluctuations without trend.' In France since the 1980s, the salaried middle classes have tended to support the Left, compensating for the drop in support by the working-class, which is attracted by the extreme right embodied by the National Front (Gougou and Mayer, 2012). In the United States, Hout, Brooks, and Manza disputed Clark, Lipset, and Rempel's claims about the declining political significance of social class by showing the historical realignment in presidential post-War elections since 1968, as professionals and nonmanagerial white-collar workers moved from supporting the Republicans to voting for the Democrats (special issue of *International Sociology*, 8(3), 1993, on class voting). And the multiplication of large-scale electoral survey-data bases allows for systematic comparisons (Knutsen, 2006; Thomassen, 2005; Brooks et al., 2006). A major realignment taking place today in Europe could also be the growing support of the working class, yesterday a stronghold of the left, for the populist radical rights (Oesch, 2008; Rydgren, 2012).

The Resilience of the Religious Cleavage

The effect of religion on votes is even more difficult to measure than the effect of class, owing to the diversity in religious denominations and beliefs from one country to another. Yet roughly, religious integration makes voters more likely to support conservative parties. Abramson et al. (1999) have constructed the equivalent of an Alford index measuring the difference between the proportion of Protestants and non-Protestants voting for the Democrats in the United States. On the basis of a more sophisticated measure based on log odds ratios, Brooks and Manza (2004) confirmed the permanence of an electoral religious cleavage, opposing Protestants, who vote more commonly for the Republicans to Catholics, Jews, and secular voters, who prefer the Democrats. It has just slightly eroded because of the growing heterogeneity of the Protestant group, Republicans losing the support of the more liberal on issues of abortion and sex who tend to turn to the Democrats, contrary to the more conservative Evangelical Christians. More recent studies confirm the growing religious polarization of the American electorate (Putnam and Campbell, 2012).

In Europe, it is the combination of church involvement and religious denomination that influences the votes. On the whole, Christian voters are more likely to vote for the right, and support for the right increases with their degree of church attendance (Broughton and ten Napel, 2000; Knutsen, 2004; Dargent et al., 2009). In Catholic countries and mixed, bireligious contexts such as the Netherlands, the effect of religion is higher than the class effect, whereas in northern Protestant countries and in England, class comes first.

New Social Divides

Beyond the 'old' variables like religion and social class, other dividing lines have gained importance, and they are linked to ethnicity, gender, or age.

The Evolving Gender Gap

The term gender gap was coined at the time of the election of Ronald Reagan in the 1980 American presidential race, when women, for the first time since they had the right to vote, gave more support to the Democrats. Since then this gap has persisted, and there is a robust relationship between gender and vote, still significant after controlling for age, class, race, and religion (Manza and Brooks, 1998). As shown by Inglehart and Norris in *The Rising Tide* (2003), a similar gender gap has developed in most postindustrial democracies, women moving more to the left than men, whatever the indicator used (Giger, 2009). It has also been called the 'modern gender gap,' in opposition to the previous 'traditional' gender gap. In the first phase, just after being granted the right to vote, women tended to be more conservative and give more support than men to right wing parties with traditional views of women's roles. This inversion of the gender gap was attributed to their rising level of education and their massive entrance in the labor market, on the one hand, and to the process of secularization and the emancipating influence of post-materialist values and feminist movements on the other, encouraging autonomy and self-expression, especially among the younger generations, leading Pippa Norris to qualify it as the 'generation gender gap' (Norris, 1996).

Since the 1980s, though, at least in Europe, the electoral boom of far-right anti-immigrant parties has brought about a new cleavage, women appearing more reluctant than men to give them their votes. Hans-Georg Betz (1994: 142–148) was the first to outline the phenomenon in his seminal study of the radical populist rights in Europe and the difference persists. Socioeconomic and attitudinal factors have been put forward to explain this new 'Radical Right gender Gap' (Givens, 2004). Men would more often than women be 'globalization losers', overrepresented in manual unskilled works and more exposed to economic competition with migrants than are women, who are overrepresented in nonmanual jobs and public service. Women, even if a process of secularization is taking place, are still more religious and more frequent church goers than are men, and the xenophobic and antiegalitarian message of the far right parties has been repeatedly condemned by the Christian churches. There is the impact of feminist ideas, slowly progressing at all levels of society, especially among the younger generations, which would prevent women from supporting parties with traditional ideologies, reducing them

to their roles of spouses and mothers. There is an image of verbal and physical violence attached to these parties that would particularly repel women.

But other studies have lately foreseen a possible decline of the radical right gender gap, as in France, where in the 2012 presidential election for the first time, after controlling for age, education, political orientation, and religion, gender had no impact on support for Marine Le Pen, the new chair of the National Front. Religion could be a less protective shield at a time when Islam is presented as a cultural threat to Western Christian values. The economic situation of women has deteriorated, and there is an unskilled female-service proletariat symmetrical to that of the male, manual working class, where economic insecurity fuels anti-immigrant resentment. Last, parties like the Party for Freedom in the Netherlands or the-Norwegian Progress Party are giving a feminist touch to their crusade against Islam, which is presented as a religion of fanaticism and intolerance. They claim they defend the rights of women beaten, mutilated, and ill treated by Muslim men (Akkerman and Hagelund, 2007). In France, Marine Le Pen, the newly elected president of the National Front, is taking a similar turn. This could in the long run considerably expand the electoral base of the far right.

Race and Ethnicity

The electoral impact of race was first studied in the United States, where an African American identity emerged after the Civil War. Black voters first supported the Republican, Lincoln, and his antislavery party. But the New Deal first, then in the 1960s the struggle for civil rights, brought about a major party realignment along the race issue (Carmine and Stimson, 1989), the blacks supporting the Democratic party, champion of civil liberties, and the white Southerners turning to the Republicans. Ever since, African American voters have massively voted for the Democrats, more than 95% supporting Obama in the 2008 presidential election. As shown by Michael Dawson (*Behind the Mule*, 1994), the memory of collective struggles and the feeling of a shared community of destiny unifies the group, and race counts more than class. One finds a similar pattern of ethnic voting among other minorities: in 2008, according to a New York Times/CBS exit poll, 62% of Asians and 67% of Hispanics voted for Obama, compared with 43% of white voters.

In Europe, the field of research into ethnic voting is quickly expanding too (Givens and Maxwell, 2012), even in France, where for a long time, the color-blind republican model was an obstacle to public assertion of ethnic identities. The pioneer survey conducted by Sylvain Brouard and Vincent Tiberj (*As French as Anyone Else?*, 2011) in a sample of French citizens of Maghrebin, African, and Turkish origin, 60% of whom are Muslims, shows massive electoral support for the parties of the Left, controlling for occupation, income, age, gender, and education.

The last Ethnic Minority British Election Study following the 2010 election tells the same story: Black and minority ethnic people, who represent some 8% of the electorate, remain highly supportive of the Left and its egalitarian and universalistic values, with more than two-thirds voting Labor and up to 80% of African and Caribbean people voting Labor.

The Generational Gap

Age cuts out distinct generations whose members are born at the same time, go through the same events, start voting at the same moment and, in certain contexts, can develop a form of group identity. Taking the French case as an example, Louis Chauvel (2006) analyzes the unequal life chances of three distinct generations: the pre-War generation, who went through the world conflict and the depression; the privileged baby boomers, who benefited from a period of peace and prosperity, better educational opportunities, full employment, rising social benefits, and upward mobility; and the post–baby boom generation, who became adults in a context of recession, when the welfare state was in crisis, unemployment was rocketing, income was stagnating, and the risks of downward mobility were increasing. The political consequences are that post–baby boomers stand apart by their low level of conventional involvement in politics (electoral turnout, party proximity, political interest) contrasting with their high potential for protest and contentious politics. In the long run, in an aging society, this could lay the foundations for generational conflicts. Of course, youth does not form a unified group; ethnicity and access to education and jobs draw strong lines of cleavage among them. But the context of global recession, which has hit young people primarily since 2007, could fuel their resentment and amplify the divide.

These lines of cleavage make sense only if one articulates them; the same person has multiple identities, and one of them will be most salient in the specific context of the election. The concept of intersectionality, coined by feminists, is one way to think about these different forms of domination together, linked to race, gender, and class. Another approach is the total social cleavage index used by Manza and Brooks (1997) to capture the global effects of class, religion, race, and gender on presidential votes in the United States, controlling for age, education, and region. It shows, paradoxically, that from 1962 to 1992, the level of the global index remained stable. There is always a social logic to politics (Zuckerman, 2005). What changes is the respective weight of the variables; there was a spectacular rise in racial cleavage after the 1960s, followed by gender.

Cultural Cleavages

Another expanding field of research, started by Inglehart's seminal work on postmaterialism and Herbert Kitschelt's work on the axes of party competition in Western Europe (Kitschelt and McGann, 1995), explores the growing electoral impact of the second dimension of politics. Yesterday, left and right opposed each other on economic issues and on the degree of state intervention and regulation. With the rise of post-materialist values carried by New Left and Green parties, and the backlash against these same values carried by New Radical Rights, the political debate has shifted toward noneconomic issues, such as abortion, sexual minorities, and Christian values in the United States and immigration, multiculturalism, and national identity in Europe. Actually, "Class is not dead – it has been buried alive under the increasing weight of cultural voting," as shown by Van der Waal et al. (2007). Workers who support the far right are in favor of a strong social state, like

the left-wingers, but when the time to vote comes, the main issue in their eyes is immigration, which is seen as an economic, cultural, and political threat. And that is why class is less significant than education when explaining these votes, tightly correlated as they are with the degree of authoritarianism vs libertarianism (Bornschier, 2010). A similar debate is taking place in the United States. Larry Bartels (2008) finds no rise in cultural voting in the working class; on the contrary, he observes a growing gap between high- and low-income people in terms of the level of support for the Democrats.

The Role of Emotions

A last challenge for both the rational choice and the social psychological approaches of voting comes from the neurosciences and a growing field of research revisiting the role of emotions. The pioneer experimental work of political psychologists such as George Marcus in *Affective Intelligence* (Marcus et al., 2000), exploring the emotional foundations of political cognition, showed that anxiety, paradoxically, makes voters more rational. If 'normal' votes rely on habit, going with the preferred party, in a context of crisis or tension, voters tend to reassess their positions, look at candidates and platforms with critical eyes, and eventually vote differently from their party identification. Yet authors such as Drew Westen in *The Political Brain* (2007) and Jonathan Haidt in *The Righteous Mind* (2012) reach the opposite conclusion. Passions, feelings, deeply ingrained values, and moral intuitions count more than rational argument and deliberation when the time comes to take sides. The debate is open.

The Puzzle of Electoral Participation

An analysis of voting choice would not be complete without taking into account the alternative behavior: not voting. Whatever the election, a sizable number of eligible citizens are not registered or choose not to go to the polls. The proportion ranges between less than 5% in countries where voting is compulsory and 40% or more in Switzerland and in the United States.

The Socioeconomic Status Model and Beyond

Whatever the country, the profiles of these nonvoters, revealed by aggregate as well as survey data, are quite similar. Educated voters and members of the upper and middle classes participate more than the uneducated and the working classes, and middle-aged voters go more willingly to the polls than the very young or the very old. What has become known as the socioeconomic status (SES) model (Verba and Nie, 1972) postulates that well-integrated and upper-status individuals are more likely to participate because they have more resources to invest in politics – time, money, information, and networks – and because they are more likely to develop civic attitudes (see Almond and Verba, *The Civic Culture: Political Attitudes and Democracy in Five Nations*, Princeton, NJ: Princeton University Press, 1963) that predispose to do so, such as interest in politics, a sense of duty, and a feeling of political efficacy. Political participation is socially skewed. There are compensating factors, however, such as group consciousness or ethnic awareness. With the development of feminism, the difference between female and male turnout rates has disappeared, and black political empowerment in the United States since the Voting Right Acts has reduced the difference between whites and African Americans, the latter participating even more than whites when differences in SES are taken into account (Verba and Nie, 1972).

Last, as pointed out by Verba et al. (1995), if people do not participate it is not only because they cannot, they lack the necessary skills or money, or they do not want to, because they are not interested; it is also because 'nobody asked them to.' They are isolated from the networks – churches, associations, unions, and formal and informal groups – that mobilize people. They lack social capital, in the sense given to it by Robert Putnam (2000), as a vector of civicness. Conversely, Braconnier and Dormagen (2007) explain the dramatic drop in voting turnout in the former 'red' suburbs of Paris by the disappearance of the Communist Party networks that used to structure and mobilize the neighborhood.

The Puzzle of Participation

On the whole, the increasing education level of the electorate and the growth of the middle classes should gradually raise electoral participation in postindustrial societies. But paradoxically, the opposite is happening. There has been a clear drop in turnout rates in most established democracies (Franklin, 2004).

This participation puzzle has revived interest in rational choice models. Because one vote has but an infinitesimal influence on the electoral outcome, the rational behavior, at first sight, would be to not bother going to the polls, and since Downs, a large body of literature has been devoted to what appeared as the voting paradox. It can be understood only if one extends the notion of rationality and if one admits that voting, like most human actions, is guided not only by interest (instrumental rationality) but also by principles and values (axiological rationality) (Boudon, 1997). At the beginning of the twenty-first century, along the same line, several studies have tried to solve the paradox of nonvoting (for a summary, see Blais, 2000). Some studies focus on the costs and benefits of voting turnout and particularly institutional factors, such as registration formalities, compulsory voting, electoral rules, party competition, and all the political factors that facilitate or make meaningless the act of voting (Norris, 1998). Others, in line with Harold Gosnell's pioneer experiments in Chicago in the 1923 elections (*Getting Out the Votes*: *An Experiment in the Stimulation of Voting*, San Francisco, Greenwood Press, 1977) explore what can best induce citizens to perform their civic duty, intrinsic satisfaction derived from behaving in accordance with the norm, or extrinsic incentives to comply. A large-scale field experiment involving several hundred thousand registered voters used a series of mailings to test these two hypotheses. Turnout was much higher among those who received mailings promising to publicize the turnout to their households or their neighbors than among those who were simply reminded of the civic importance of voting, which demonstrates the decisive importance of social pressure (Gerber et al., 2008).

Another line of research sees nonvoting as a deliberate strategic behavior, expressing political discontent with the electoral choices available, even though those who do not vote have levels of education and political interest that are above average, and they are politically 'in the game' (Jaffré and Muxel, 2000). Studies of electoral turnout detecting nonvoters on official voting records, such as the series conducted in France by the National Institute for Statistics and Economics Studies, more reliable than survey data because voters are reluctant to confess what is considered an uncivic behavior, confirm the rise of intermittent voting, driven by the political context. Along the same lines, the large-scale comparative survey conducted by Mark Franklin (2004) in established democracies shows clearly that the primary factor explaining declining turnout is the lack of political competitiveness. People vote when they think their voices count.

The Challenge of Genopolitics

The latest challenge in the field of electoral sociology comes from a new research subfield, genopolitics, at the crossroad of political science and behavior genetics. An article by Alford et al. (2005) opened the way, claiming that genes count more than environment in explaining ideological orientations, specifically how one becomes a conservative or a liberal. A host of studies has followed, usually based on the methodology of twin studies, comparing the political behaviors and attitudes of genetically identical twins with the same DNA, to nonidentical twins. If the identical pairs show the same political behavior, it would mean that this behavior is heritable, and genes explain its variations. For instance, in a recent article in the *Journal of Politics*, Fowler and Dawes (2008) claim that they have found two genes predicting voting turnout. The study is based on the third wave of the National Longitudinal Study of Adolescent Health (2001–02), from which they extracted a sample of sibling pairs who answered questions, among others, about civic participation, partisanship, and religion and provided genetic material. The results are not totally convincing as yet. A critical review of this study written by Charney and English for the *American Political Science Review* (2012) points to several weaknesses, questioning their indicators of voting turnout, of population stratification, of genotype classification, of independence of cases and controls, and of the ignorance of the recent paradigm shift in the field of genetics.

The three models we started with have changed considerably. Born in the behavioral era, they were reformulated by the cognitive neurosciences, for which affects, group belonging, party identification, or the state of the economy are cues, among others, that help voters to orient themselves in the political space. They might benefit from the new challenge coming from the advance of behavior genetics. Meanwhile, the rising number of emerging or transitional democracies since the mid 1970s, as well as the multiplication of cross-national data bases – Eurobarometers, Central and Eastern Eurobarometers, Latino Barometro, Latin American Public Opinion Project, Afrobarometer, Asian Barometer, Arab Democray Barometer, etc. – provide fresh opportunities to enlarge the scope of electoral studies and test in various political cultures the validity of theories and concepts elaborated in Western democracies. It could also be an occasion to explore what most studies leave aside: the noninstrumental meanings the act of voting can take, from one context and one epoch to another. Although the political outcomes of elections are essential, they also have ritual, expressive, and social functions, as shown by Yves Deloye and Olivier Ihl in their major book, *The Act of Voting* (2008), and its evolution over two centuries.

Voting: Turnout

Benjamin Highton, University of California, Davis, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Understanding why people vote and why some countries have higher turnout than others requires a consideration of the expressive nature of voting and the costs and benefits it entails. This makes it possible to explain empirical regularities in turnout patterns. Contrary to conventional wisdom, it does not appear that universal turnout would alter election outcomes very much.

Why do some people vote and others do not? Why do some countries have higher turnout rates than others? Would election outcomes change if turnout levels were higher? These are the primary questions that concern students of voter turnout.

Factors That Affect Turnout

With one caveat, a useful approach to explaining turnout rates of either individuals or countries entails considering the costs and benefits of voting. The caveat reflects the observation that any single vote "is lost in a sea of other votes" (Downs, 1957: 246). Paul Meehl clearly identifies the implication of 'this big brute fact,' namely that "my chances of determining who becomes President [or influencing just about any election outcome] are of about the same order of magnitude as my chances of being killed driving to the polls—hardly a profitable venture …. [Voting] is irrational as an instrumental action toward an egocentric end" (Meehl, 1977: 11). To make any headway in explaining voter turnout, one must recognize that there are intrinsic or expressive benefits to be gained from voting that do not depend on whether one's vote is decisive for an election outcome. Without this expanded conception, there can be no coherent explanation for why so many people choose to cast ballots.

The significant factors that affect the costs and benefits of voting may be usefully characterized as either of the institutional or individual variety. There are two primary types of institutional variables. *Laws* that specify the registration process, the type of election districts, and the structure of the national legislature, all influence turnout. *Political characteristics* like the degree of disproportionality in the translation of votes into seats and the number of political parties represent another set of institutional characteristics that affect turnout.

With regard to individual characteristics, although any examination of the vast turnout literature will reveal a plethora of factors, three stand out. Although the size of the difference varies, in virtually every election context the better educated have higher turnout than those who are less educated; older people have higher turnout than the young, although turnout typically dips among the oldest eligible voters; and those who are more interested in politics have higher turnout than those whose interests lie elsewhere. The explanation for these patterns may be found in a consideration of the costs and benefits potential voters face.

The Costs of Voting

Focusing first on the costs that people must overcome in order to vote, empirical research shows that the higher the costs, the lower the turnout. Two primary costs should be considered. First, some countries have 'compulsory voting,' imposing penalties like modest fines for nonvoting. Turnout in these countries is notably higher. The second significant cost of voting is deciding for whom or what to vote. Commonly referred to as 'information costs,' people must gather or be given sufficient information to decide how they will vote. It is a cost that can be easily overlooked, because for "people already well informed, keeping up with politics is scarcely dull, is almost effortless, and the notion that information costs something seems almost peculiar" (Converse, 1975: 97). Yet for many individuals, politics is at most a peripheral concern. For these less interested people, information costs are higher and their turnout is consequently lower.

Information costs for potential voters are also reduced if they are undertaken by someone or something else. In this regard, candidates and political parties are extremely useful. Voter mobilization efforts reduce information costs because they diminish the need for people to gather for themselves the necessary information in order to make their decisions. Consequently, factors that provide candidates and parties incentives for broad based mobilization efforts, like nationally competitive electoral districts, close elections, and lower levels of disproportionality in the translation of votes to seats, all have the effect of boosting turnout by bringing down information costs for potential voters.

The Benefits of Voting

Even in a political context where voting costs are minimized, they are never eliminated; "voting is inherently costly" (Downs, 1957: 265). It is therefore necessary to consider the benefits citizens derive from voting in order to explain why anyone casts a ballot at all. The 'big brute fact' that a single vote has virtually no effect on an election outcome leads to the observation that "most of the action is, in fact, in the intrinsic values of voting per se" (Aldrich, 1993: 266). The notion that one has a duty to vote pervades most democracies. Schooling is one way this norm in inculcated and provides a reason why the better educated have higher turnout. In addition, those who are more

interested in politics gain greater intrinsic satisfaction from voting because they are more engaged with the political system.

One of the most significant new directions in the study of the voting benefits and turnout has been the use of field experiments to analyze voter mobilization – or get out the vote (GOTV) – strategies (Green and Gerber, 2008). This research began with the question of whether in-person voter canvassing is more effective at mobilizing voters than phone calls or direct mail and has proceeded to examine a wide range of tactics and methods that might motivate people to vote. Two of the most important areas of research are partisan versus nonpartisan GOTV appeals and the influence of various forms of social pressure on turnout. Importantly, because this research is based on field experiments, employing random assignment of treatment conditions, the causal claims that follow from are more persuasive than other research on individual motivations based largely on observational data.

The association between institutional characteristics and the benefits of voting is less intuitive, but is empirically evident. Voting is more gratifying when there is a stronger connection between election results and government formation. The relationship is weaker in countries with more political parties where postelection coalition building is far more frequent and complicated, and turnout is lower. Similarly, in countries with unicameral national legislatures, the consequences of election outcomes are more decisive for governing, and people are therefore more likely to perceive elections as meaningful and vote (Jackman, 1987).

The Implications of Nonvoting

In any country without universal turnout, some groups will have higher turnout than others. Compared to their proportion of the population, some will be overrepresented, while others will be underrepresented in the voting population. Because even countries with compulsory turnout fall short of universal turnout, the effects of nonvoting for election outcomes and governmental policy must be considered. The potential political implications are sufficiently significant that they were the topic of Arendt Lijphart's Presidential Address to the American Political Science Association in 1996, "Unequal Participation: Democracy's Unresolved Dilemma."

Two factors determine the consequences of nonvoting. First, the difference between the preferences of voters and nonvoters must be considered. To the extent that what nonvoters want differs from the desires of voters, then the representation of interests in the voting population will be a distortion of the interests of the larger population. If voters and nonvoters have similar preferences, then the degree of distortion will be less. The second important consideration concerns the relative size of the nonvoting population. If the number of nonvoters in an election is small compared to the number of voters, then even if nonvoters have a very different set of preferences, their small number will limit the potential for impact on the aggregate preferences of voters. On the other hand, where nonvoters are more numerous, their potential influence grows.

Several examples illustrate the interplay between nonvoters' preferences, the size of the nonvoting population, and implications of nonvoting. In the United States, after the Voting Rights Act of 1965 and the widespread dismantling of legal and extralegal barriers to black suffrage in the southern states, large numbers of African-Americans entered the voting population. Their preferences were quite different from those of white voters, thereby spurring the political realignment in that region of the country. In contrast, when the United States (in 1919) and Switzerland (in 1971) extended the right to vote to women, similarly large-scale political change did not ensue. Although the enfranchisement of women added larger numbers of voters, their preferences were not especially distinctive, and as a result there were minimal electoral consequences.

In the current political era, the potential implications of nonvoting are greatest in the United States because turnout is comparatively low and the connection between socioeconomic status and turnout is relatively strong. The actual consequences, however, do not appear to be great. Examining presidential and senatorial elections in the United States, Sides et al. (2011: p. 294) report that "universal turnout would tilt the electorate only very slightly in a Democratic direction rather than generating an enduring liberal majority." More generally, analyzing party vote shares across 25 democracies. Bernhagen and Marsh (2007: p. 558) report results "consistent with the bulk of research implying rather mild effects of increased turnout."

To conclude, voter turnout is shaped by both individual and institutional factors. Explaining the connection between these factors and the decision to cast a ballot requires a consideration of the costs and benefits facing potential voters. Because the costs and benefits are not identical for all people, different groups vote at different rates. As a result, there is a possibility that the preferences of voters will not be representative of the entire population. To be sure, this sort of distortion is sometimes evident, but its magnitude is typically modest.

Vygotsky, Lev Semenovic (1896–1934)

René van der Veer, Center for Child and Family Studies, Leiden University, Leiden, The Netherlands

© 2015 Elsevier Ltd. All rights reserved.

Abstract

After a brief account of Vygotsky's life, this article discusses four of Vygotsky's fundamental ideas: that (1) higher mental functions are originally shared between persons; (2) inner speech derives from communicative speech; (3) word meanings are not stable in ontogeny and can be influenced by education; and (4) individual task performance can be predicted by characteristics of previous joint task performance. It is shown that these four and interconnected ideas still inspire modern research.

Introduction

In this article the life and work of Lev Semenovich Vygotsky (1896–1934) is discussed. After a brief overview of his life, attention is paid to four of his fundamental ideas: (1) the sociogenetic law, that is, the idea that all higher mental functions are originally shared between persons and only subsequently become private; (2) the idea that the origin and properties of egocentric and inner speech can be derived by studying the development of children's communicative speech; (3) the idea that word meanings undergo a process of development and that children's everyday concepts can be enriched by teaching them scientific concepts in school; and (4) the zone of proximal development, that is, the idea that joint performance is predictive of independent performance, whether in the context of intelligence assessment or in the context of educational settings. It is concluded that Vygotsky's legacy still inspires much of contemporary research in the humanities.

Biography

Lev Semenovich Vygotsky was born on 5 November 1896 in Orsha as the second child to a secular Jewish family and spent his youth in Gomel in Byelorussia. He received private tuition and only entered school at the age of 15 years to follow the last two years of a private Jewish gymnasium. Having finished school, he moved to Moscow to study law at the Moscow Imperial University and humanities at the Shanyavsky University. He finished his studies at Shanyavsky University with a master's thesis on Shakespeare's *Hamlet* and returned to Gomel to engage in a wide variety of activities (Vygodskaya and Lifanova, 1996).

His interests at the time were divided between two areas. First, since his childhood he had been fascinated by literature and theater. During his university years he had pursued these interests, taking courses in literature and linguistics, attending the plays in Stanislavsky's Art Theater and Tairov's Chamber Theater, and writing theater and book reviews for literary journals. Second, taking Pavel P. Blonsky's courses on education and psychology at Shanyavsky University had quickened his interest in problems of a psychological nature (Feigenberg, 1996). His activities in Gomel reflected these two broad areas of interest. During these years (from 1917 to 1924), Vygotsky worked as a literary critic for local newspapers, taught different subjects (e.g., literature, philosophy, and psychology) at various schools of different levels, cofounded a short-lived publishing house and an equally short-lived literary journal, and worked for the Gomel authorities as the official responsible for the cultural life of the town. In this latter capacity he contracted theater groups, held lectures on topics of general interest, and organized poetry evenings (Van der Veer and Valsiner, 1991).

While in Gomel, Vygotsky became interested in the way the formal properties of a literary text evoke aesthetic experiences in the reader. This led him to deepen his interests in psychology, as did his experiences as a teacher of children and adults of highly different abilities and penchants. He installed a simple psychological laboratory at the normal school where he was teaching and conducted his first empirical psychological investigations. His account of these investigations at a congress led to an invitation by Luria to come and work as a psychologist at Moscow University. His Ph.D. thesis *The Psychology of Art* (Vygotsky, 1925/1971) gives a perfect overview of his early views.

Having arrived in Moscow in 1924, Vygotsky again displayed a wide variety of activities. During what was to be the past decade of his life he worked as a clinical psychologist, carried out empirical studies with children, held teaching positions at various universities, cofounded several scientific journals, headed research institutes, worked for publishing houses, and published a couple of hundred books and articles on widely diverging topics. His interests transcended narrow disciplinary boundaries. He began, for example, studying the semiotics of cinematic language with the film director Sergej Eisenstein, he developed a test to study the thinking of schizophrenics, he lectured on the problems of blind and deaf children, he initiated research into memory development, and he developed an interest in what is now called neuropsychology. In 1931, while already a full professor of psychology, he began studying medicine. However, on 11 June 1934 Vygotsky died in Moscow of tuberculosis, a disease that had haunted him for the better part of his adult life.

The writings of Vygotsky were virtually unknown outside Russia until the publication of *Thought and Language* (Vygotsky, 1962) in English stirred international interest. Nowadays a substantial part of his writings are available in English translation (Van der Veer and Yasnitsky, 2011) and the international discussion of the origins, merits, and shortcomings of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61134-0

Vygotsky's ideas has got a new impetus (Miller, 2011; Yasnitsky, 2011; Zavershneva, 2010).

Main Ideas

Given his interest in literature and language, it comes as no surprise that Vygotsky (1962, 1994) attached great importance to language in his psychological thinking. Like other thinkers, he held that the use of language (speech, in his terminology), together with the manufacture and use of tools, is a distinguishing characteristic of humans. In his view, all truly human, higher mental processes involve the use of speech.

From Dialogue to Self-Regulation: The Sociogenetic Law

The original function of language is communication, Vygotsky (1997a) argued. Children and adults communicate their intentions and steer or guide the behavior of the social other. This communicative process is at first very asymmetric in that the adults do most of the guiding and attribute meaning – at first often counterfactually – to the infants' utterances. Very soon, however, children become able to use words to accomplish things and, most importantly, to steer their own behavior. Self-regulation thus originates in dialogue.

A simple example is that of a child learning to cross a street. In a first stage, caregivers will tell the child to watch out carefully and children will simply follow this instruction. In the next stage, the child will say aloud to watch out and thus instruct itself. In the final stage, the child will merely think this instruction. Thus, a process that was originally shared between two persons, an interpsychological process, has become an individual, intrapsychological process. The child is applying to itself what was first applied by others and thereby mastered its own behavior through the use of conventional signs. With Baldwin, Janet, Royce, and others, Vygotsky (1997a) claimed that all higher mental processes are originally shared between persons, and he coined the developmental transition from inter- to intramental processes the sociogenetic law.

This example is linked with another phenomenon that Vygotsky discussed in his writings, namely that of the intersection of thought and speech. In his view, thought and speech have different genetic roots and only merge to form verbal thought or intellectual speech at a later stage in phylogenetic and ontogenetic development. Thus, in human children both preintellectual speech (i.e., babbling) and preverbal thinking (e.g., infants expect to find an object where it was hidden previously) can be observed, while in the phylogenetic domain one sees animals solving simple problems (e.g., using an artifact to reach a goal) and displaying primitive communicative means (e.g., expressive movements). It is only in humans, however, that speech and problem solving merge to form the powerful capacity of verbal thought. Problem solving now no longer proceeds in the visual field, Vygotsky (1997b) argued, but in what he called a 'semantic field.'

Egocentric and Inner Speech

Vygotsky claimed that speech develops in an intrapersonal situation, and subsequently it is used to steer the self-received additional support in studies of the phenomenon of egocentric speech. It was Piaget who first described the phenomenon of children who while carrying out some activity speak for themselves in a way that is often not intelligible to others. Piaget hypothesized that such speech does not take account of the viewpoint of the social other and reflects younger children's general inability to transcend their own point of view. In his view, children are at first unable to see the world from another perspective than their own and only gradually realize, under the pressure of their peers, that theirs is a specific viewpoint.

Vygotsky criticized Piaget's interpretation of the phenomenon of egocentric speech and conducted a series of experiments to argue that children's egocentric speech is social in the sense that it addresses social others (Van der Veer and Valsiner, 1991: 363–369; Vygotsky, 1987). He noted that egocentric speech is absent or greatly reduced when the child is alone (which suggests that it is meant for others) and that its incidence rises when the child is confronted with unexpected problems (which suggests that it has some function in the solution of problems). He also observed that egocentric speech becomes less intelligible as the child grows older. This set of results led him to posit that egocentric speech (1) originates in normal, communicative speech and branches off at a later stage; (2) has as its function to steer the child's behavior when the need arises; and (3) becomes less and less intelligible for the outsider until it becomes proper inner speech. Egocentric speech, then, is an intermediate stage between normal, communicative speech and inner speech. Like communicative speech, it is audible, and like inner speech, it serves to guide the child's thinking.

Vygotsky went on to speculate about the properties of inner speech. He argued that its syntax must be special: it is speech that is abbreviated and tends toward predicativity, that is, omitting the subject of the utterance. He also suggested that inner speech has special semantic properties: personal sense dominates over dictionary meaning. He thus believed to have demonstrated that, in the process of becoming private, speech undergoes a series of transformations.

Word Meaning and Conceptual Development

Above it was said that children use conventional signs to regulate their own behavior. Toward the end of his life, Vygotsky began emphasizing that the meanings of these conventional signs or words change over time. Children use the same words as adults do to designate specific objects but the meaning of these words may be quite different. Thus, in the child the word 'farmer' may evoke picture book images of a person taking care of cattle and growing crops, while adults may think of an entrepreneur who tries to maximize profit. Using various strategies, Vygotsky tried to prove experimentally that a mature understanding of many concepts is only reached in adolescence. In this connection, he introduced a distinction between mature, academic, or scientific concepts, on the one hand, and immature or everyday concepts, on the other hand. Supposedly, the academic concepts express the true nature of things and are linked to other similar concepts. Together they form a coherent network covering a field of knowledge. Academic concepts are taught at school. Everyday concepts, on the other hand, often focus on irrelevant features of some

subject and together form a disconnected whole. Everyday concepts are more or less independently acquired by children in informal settings.

Vygotsky's basic idea was that academic concepts and everyday concepts mutually enrich each other. The everyday concept of a farmer becomes enriched because the child learns the nonapparent fact that farmers take part in a market economy and try to realize certain goals. The child's academic concept of a farmer is enriched because the abstract notion of entrepreneurs dealing with cattle and crops is filled with concrete facts of daily farmer life and thereby gets body and flesh. Thus, academic concepts presuppose everyday concepts, build upon them, but once acquired by the child they alter its everyday concepts in fundamental ways. The result of the interplay between everyday and academic concept is an elaborate and rich notion of the concept of farmer. Vygotsky (1935) speculated that the introduction of systems of academic concepts in school would restructure the child's whole style of thinking; that is, he assumed that the introduction of such concepts in specific subject areas would generalize to other areas. Education leads development, as he used to put it. Instruction in the school setting propels child development along lines that are each time specific for a certain culture or society.

Predicting Mental Growth: The Zone of Proximal Development

In several lectures delivered in 1933, Vygotsky transposed the sociogenetic law to the domain of cognitive assessment and prognosis. He claimed that if one were to measure what the child is able to do in cooperation with someone else (interpsychologically), one would be able to predict what the child can do independently (intrapsychologically) later on. At any given moment, both the child's dependent (e.g., with hints from an adult) and independent performance on an IQ test can be measured. The difference between the two IQ scores yields an indication of the child's cognitive potential. Some children will be able to profit more from adult hints and will improve their independent score more substantially than others. These children show the richest developmental potential, Vygotsky (1935) argued. To measure what children can do independently is to measure what they can do already. To measure what children can do with the help of an adult is to measure what they will be able to do in the near future, in what Vygotsky coined their zone of proximal development. In this way, he criticized the contemporary use of IQ tests and suggested a procedure for the assessment of cognitive potential (Grigorenko and Sternberg, 1998).

Relevance for Contemporary Science

Vygotsky's ideas inspired an enormous and still growing amount of research, both in and outside the former Soviet Union (Miller, 2011).

Wertsch (1985) tried to corroborate Vygotsky's view that self-regulation develops in dialogue by investigating mother–child joint problem solving. He and others have also advanced proposals to fuse Vygotsky's ideas on dialogue and its relevance for self-regulation with those of Bakhtin.

Vygotsky's view of the nature and function of egocentric and inner speech has become a hotly debated topic and has been developed further by others (e.g., A.A. Leontiev, A.R. Luria, and A.N. Sokolov). The Eastern European research is well represented in Sebeok (1968), Slobin (1966), Prucha (1983), and Wertsch (1978). Zivin (1979) gives a representative account of both the research tradition initiated by Vygotsky and Luria and its Western counterparts.

Vygotsky's concept of word meaning and his view of the dialectic interplay between academic and everyday concepts in education have also led to a whole research tradition. An excellent and critical account can be found in Wertsch (1985), while Van der Veer and Valsiner (1991) have traced how Vygotsky's research into the development of concepts was used by Western clinical psychologists to diagnose various groups of mental patients (e.g., schizophrenics and patients suffering from aphasia).

The concept of the zone of proximal development has inspired an immense number of publications. These can be divided roughly into two groups. The first group consists of publications that deal with the influence of education on development. It is analyzed, for example, how classroom discussions can promote a zone of proximal development in students, or what kind of teaching is needed to promote children's use of language for self-regulation. An overview of this kind of work can be found in Moll (1990). The second group consists of publications dealing with the assessment of learning potential. In this approach the zone of proximal development is used as an individual difference metric designed to provide information about individual students; that is, Vygotsky's original idea to measure aided and unaided performance on some IQ test is operationalized, and it is investigated whether such repeated measurements yield important prognostic information (cf. Grigorenko and Sternberg, 1998).

All in all, it can be said that although many of Vygotsky's ideas are debatable (see Van der Veer, 2014) and will have to be discarded or refined, they nevertheless have inspired a great and still growing number of researchers in the humanities. In itself this is remarkable for a man who published very little in languages other than Russian, who died more than 60 years ago, and whose international fame began only 30 years after his death. The fact that Vygotsky's legacy still inspires contemporary research marks him as a true classic thinker of the humanities.

Abstract

This article will focus on describing the main tenets of Vygotsky's theory of human development, current critique of these tenets, and new approaches to education stemming from Vygotsky's work and its critique. Vygotsky's legacy is in his emphasis on social, historical, and cultural aspects of development and learning, semiotic mediation, activity, and social interaction. According to Vygotsky, education can lead children's development and learning is shaped by cultural tools and activities in which it is embedded. This article is organized around three major interconnected issues: what develops, what are the processes of development, and what are the directions of development.

Vygotsky's legacy is in his emphasis on social, historical, and cultural aspects of development and learning, semiotic mediation, activity, and social interaction. After about 50 'dark years' of silence, from the early 1930s (immediately after his death) to the end of 1970s, caused in part by the repressive political circumstances in the Soviet Union, social sciences have been experiencing Vygotsky's renaissance. Since the 1970s, Vygotsky has become a 'root theoretician' for a family of approaches in social sciences including sociolinguistics (Heath, 1983), anthropology (Lave and Wenger, 1991), psychology (Cole, 1996; Rogoff, 1990), education (Cazden and Cordeiro, 1992), and literacy studies (Gee, 1996), among others. In fact, it is probably not an overgeneralization to say that currently, developmental psychology and education have been highly influenced by Vygotsky's work. This article will describe the main tenets of Vygotsky's theory of human development, current critique of these tenets, and new approaches to education stemming from a dialogue with Vygotsky's work. This article is organized around three major interrelated issues: what develops, what are the processes of development, and what are the directions of development.

What Develops?

Vygotsky argued that human development is based on intertwining of two lines: (1) natural based on processes of biological maturation and (2) cultural based on mastery and use of cultural means. Psychologically, these two lines are represented by lower and higher mental functions, respectively, such as memory, attention, and intelligence. For example, mechanical memorization of unrelated bits of information mainly involves lower functions of memory. Meanwhile, memorization that is based on mental structuring of information in some hierarchical classes (e.g., axe, saw, and hammer are tools) or a story connecting items to remember involves higher mental functions of memory. For instance, when a child is asked to remember the word 'theater' and a picture of a crab, the child creates a story: "The crab is looking at the stones on the bottom, it is beautiful, it is a theater" (Vygotsky, 1997: p. 181). Vygotsky insisted that higher mental functions are formed by a reorganization of lower mental functions mediated by a cultural sign (e.g., mnemonics). Higher mental functions allow a person to control his or her behavior, "in the elementary form [of memory – EM], something is remembered; in the higher form, humans remember something … the basic characteristic of human behavior in general is that humans personally influence their relations with the environment and through that environment personally change their behavior, subjugating it to their control" (Vygotsky, 1978: p. 51). Thus, according to Vygotsky, what develops is higher mental functions via a mastery of cultural signs (i.e., *semiotic mediation*), leading to a person's development of *self-regulation* and self-control.

Probably the most elaborate application of Vygotsky's stress on cultural mediation as the object of development has been in the 'sign' pedagogy developed by the Russian educational psychologist Davydov (Davydov and Kilpatrick, 1990). Davydov and his colleagues rewrote an entire elementary school curricula (e.g., math, sciences, and language art) representing it as a series of dialectical contradictions of mental actions mediated by cultural signs. They also changed the curriculum sequence putting the abstract concepts – higher level cultural mediators – ahead of concrete application of them (e.g., putting study of fraction and algebra ahead of integer arithmetic). For example, according to Davydov and Kilpatrick (1990), the fraction represents the contradiction between the permanence of the object's length (N) and the variability of its measurement (A), depending on the unit (c) mediating the measurement. Mathematical formula $A/c = N$ is a model of the fraction that allows first-grade students to make comparisons involving any measurement unit.

Yet, a growing literature has implicitly or explicitly criticized Vygotsky for making mental functions the object of development (Rogoff, 1990). This work has argued that culturally mediated functions are not self-contained, but instead embedded in sociocultural activities. Lave (1988) introducing the notion of *situated cognition* demonstrates, for example, that people's computation in school-like math tasks and grocery shopping is not psychologically equal even when the problems are mathematically isomorphic. The problem solving is mediated and structured differently in these two conditions because the problems are embedded in different sociocultural activities with different goals and different social relations. In response to these and other related findings, alternative objects of development have been proposed.

Rogoff (1990) proposes a *sociocultural approach* in which a person's participation in sociocultural activities and communities is the object of development. Development is seen as *transformation of participation* in a sociocultural activity – transformation that is socially valuable. For example, when a child whose parents had previously read books to her starts asking her parents to read a book, this change indicates a transformation of the child's participation in the reading practice. Some have argued that mediation by cultural tools and scripts pointed by Vygotsky is only a part of the developmental story and should be considered together with aspects such as social relations, division of labor, community rules and norms, and relations with other practices and communities (Engeström et al., 1999). These features of social life were often ignored in cultural research and research on child development conducted by Vygotsky and his colleagues (Vygotsky, 1978; Vygotsky and Luria, 1993).

How It Develops?

According to Vygotsky's general genetic law of cultural development, any function in the child's cultural development appears on three planes: natural, social, and psychological. Vygotsky emphasized a dynamic and emergent character of development: each plane emerges on the periphery ('in an embryonic state') of the previous plane (Vygotsky, 1997). First, a function appears on the natural plane, when a child finds him or herself in an environment and can observe the function as used by other people without the child's understanding or active participation in it. For example, in human society, people use gestures in their communication with each other and they often are inclined to (mis)interpret some of child's actions as gestures. When a very young child tries unsuccessfully to grasp a remote object, his or her caregiver may (mis)interpret it as a command gesture to bring the object to the child.

The second plane of development is social – the child is an active participant in the function socially distributed among people, although this participation may not be necessarily conventional or fully grasped by the child on his or her own and requires the involvement of other people for the participation's success. Continuing Vygotsky's example of the development of the index gesture, at some point, the young child notices that she can control adults by stretching her arm toward a desired object – the adults often bring the remote object to the child. Thus, on the social plane, the child actively participates in the social function of controlling other people rather than finding herself in the function fully organized by other people as it was on the natural plane.

Finally, on the third plane, the function transforms from external social into internal psychological. The child's command of others transforms into the index gesture controlling the child's own attention. Now the child's stretched arm controls not others but the child herself; her own attention is mediated by the index gesture. The developmental cycle is completed: the cultural higher mental function of the index gesture that initially exists only outside the child on the natural plane becomes the child's own on the psychological plane for the child's self-regulation (Vygotsky, 1997). According to Vygotsky, development involves nonlinear and systemic processes of changing relationships and organizations of mental functions.

Recently, Vygotsky's so-called general genetic law of development has been challenged on both empirical and theoretical grounds. Thus, Vygotsky's explanation of development of index gesture faces critique (e.g., Kaye, 1982) coming from recent findings that index finger extensions can be observed in infants as young as 2 months old (Fogel and Hannan, 1985; Trevarthen, 1977) and seems to be developing in relative independence from grasping movements (Fogel and Thelen, 1987). It seems to be utilized by the infant first for touching objects at about 6 months and then for an extension of the orienting response at about 11 months (Lempert and Kinsbourne, 1985). During the period between 8 and 12 months, pointing seems to shift from an exploratory to an indicating function (Fogel and Thelen, 1987). It seems that Vygotsky's model of the development of the index gesture might be still relevant for an illustration of how a misunderstanding between child and adult guides child's development (Lock, 1980). Also, Matusov (1998) has challenged Vygotsky's insistence on the mastery of solo activity and autonomous self-regulation as the acme of the human psychological development, suggesting an ethnocentric bias on the part of Vygotsky.

The issue of the relationship between development and education led Vygotsky to introduce the notion of 'the zone of proximal development' (ZPD) as the gap between actual and potential development (Vygotsky, 1978). Vygotsky offered two major interpretations of ZPD. The first interpretation is the ZPD as a gap between the psychological (i.e., completed) plane, what the child can do by him or herself, and the social (i.e., potential) plane, what the child can do with the help of more capable others (adults or peers), of development.

This use of ZPD defines 'teachability' of the child in a specific activity or in problem solving. If an activity or problem can be accomplished by the child with the help of more capable others, this activity or skill is considered possible to teach the child. If, however, the activity or skill cannot be accomplished by the child with the help of more capable others, it is considered not useful to teach to the child. Vygotsky coined the term *formative experiment* to provide methodology for the investigation of ZPD. According to this methodology, a particular higher level psychological function is formed through some kind of instruction with a more knowledgeable other or manipulation of the context and tools used by a child. The successful formation of the psychological function verifies the existence of ZPD and provides insight into the genesis of the function (Griffin et al., 1993).

Unlike Piaget, who believed that instruction should follow development based on biological maturation and a child's active experimentation with the environment, Vygotsky argued that guidance can, should, and does lead the development. Both Piaget and Vygotsky would differently define what is currently called 'developmentally appropriate curriculum.' Piaget insisted that learning is essentially an individual endeavor and that adults can only facilitate it by providing an enriched stimulating learning environment and opportunities for the children to share and discuss their egocentric thinking with each other to promote disequilibrium in the child's

thinking. Adults should not interfere in the child's individual thinking because it can only lead to imposition of the adult's ideas onto the child – what Piaget called 'sociocentrism' (Piaget and Smith, 1995). In contrast, Vygotsky encouraged adults to provide guidance and help and to engage students in activities that are beyond their individual levels of competence ('performance before competence,' Cazden and Cordeiro, 1992).

Currently, there are attempts in education to develop 'scientific instruction' using a medical model of 'educational interventions' (Hargreaves, 1996, 1997). The essence of these efforts is to develop educational diagnostics of students' skill deficits and prescribe an appropriate dose of standardized guidance providing no less and no more help to the student than is required (Newman et al., 1989). For that purpose, some researchers have tried to develop a 'ZPD test' (Dixon-Krauss, 1996; Moran, 1997) – a standardized assessment of a student's teachability. However, it is doubtful that a reliable ZPD test would be possible to develop because, as Newman et al. (1989) demonstrate, the notion of ZPD is relational. Student's teachability depends not only on the student but also on the teacher (and broader communities in which the child participates). Thus, no test of the child alone would accurately determine the child's teachability – the teacher always counts as well as broader and local contexts and activism of the child.

According to this neo-Vygotskian view, the ZPD is applied not only to the student but also to the teacher. Both the teacher and the student try to manage the uncertainty that their joint activity creates. During teacher–student instructional interaction, the student learns how to do the classroom activity, while the teacher learns how to guide the student. Each engages in their own ZPD that mutually constitute each other – the student's learning is shaped by the teacher's guidance, while the teacher's guidance is shaped by the student's ongoing learning.

The second interpretation of the ZPD offered by Vygotsky is about the activity in which the child is involved. Vygotsky argued that at different ages, different activities become leading forces in a child's development. For young children, play is the *leading activity*, "play creates a zone of proximal development of the child. In play a child always behaves beyond his average age, above his daily behavior … As in the magnifying glass, play contains all developmental tendencies in a condensed form and is itself a major source of development … Action in the imaginative sphere, in an imaginary situation, the creation of voluntary intentions, and the formation of real-life plans and volitional motives – all appear in play and make it the highest level of preschool development" (Vygotsky, 1978: p. 102). He introduced the notion of 'leading activity' as an activity that determines the child's development. El'konin and Leont'ev elaborated this notion by creating a scale of leading activities from infancy to adulthood as the base of age periodization in a given society (Griffin and Cole, 1984). The concept of age periodization has become criticized as ethnocentric by several authors (Lave and Wenger, 1991; Matusov et al., 2007a; Rogoff, 1990).

Bruner and his colleagues developed the didactic notion of 'scaffolding' in their attempts to operationalize Vygotsky's ZPD in their study of dyadic interactions involving adults tutoring children (Wood et al., 1976). Scaffolding involves a series of adult strategies that assume responsibility for children's learning, such as focusing the child on the task, simplifying the task to fit the child's current mastery, maintaining the child's motivation for working on the task, managing the child's level of frustration and risk involved in the problem solving, and demonstrating an idealized version of the required act (Rogoff, 1990). Like Vygotsky's ZPD, the scaffolding metaphor is aimed to explain the child's gaining of skills in social interaction that the child may apply later on when working alone. It focuses on how the adult fine-tunes the extent of help he or she provides the child for each successful activity outcome while viewing the child as inept, "One sets the game, provides a scaffold to assure that the child's ineptitudes can be rescued or rectified by appropriate interaction, and then removes the scaffold part by part as the reciprocal structure can stand on its own" (Bruner, 1983: p. 60).

In a critique of the concept of scaffolding, Griffin and Cole (1984) emphasize the role of the child in his or her own development, "The metaphor [of scaffolding] becomes more problematic when we focus not on the execution of a specific task but on the changes in the child" (p. 47). This concept makes it difficult to address the issue of the child's creativity, "If adult support is the universal source of a child's development, then there is a strong sense of theology – children's development is circumscribed by adults' achieved wisdom" (p. 47). If Vygotsky's concept of ZPD seems to be too focused on the child, then the concept of scaffolding seems to be too focused on the role of the adult in guidance. As a consequence, both concepts are limited by dyadic interaction between more and less knowledgeable partners. Besides, cross-cultural research on guidance suggests that scaffolding is not a universal guidance strategy (Rogoff et al., 1993).

Unlike scaffolding, the concept of *guided participation* developed by Rogoff (1990) can be applied in diverse cultural activities because it focuses on the transformation of participation guided not only by more knowledgeable partners but also by sociocultural tools, culturally defined goals and problems, and social arrangements of joint activity: "Interaction with other people assists children in their development by guiding their participation in relevant activities, helping them adapt their understanding to new situations, structuring their problem-solving attempts, and assisting them in assuming responsibility for managing problem solving. This guidance of development includes tacit and intuitive forms of communication and distal arrangements of children's learning environments; it is often not designed for the instruction of children and may not involve contact or conversation. The model is one of routine arrangements and engagements that guide children's increasingly skilled and appropriate participation in the daily activities valued in their culture" (Rogoff, 1990: p. 191).

Lave (1992, April) insists that learning is inherent to activity and an aspect of any activity. Learning occurs even despite expectations and wills of experienced members of community – it is not a matter of whether students learn in school but a matter of what they learn. The students

might actually learn what they were not expected to learn and might not learn what was expected for them to learn. Learning is not an independent activity among other activities but, like development, it is an aspect of any activity in the world.

Lave and Wenger (1991) argue that learning is situated in *communities of practice*. Learning is always a question about membership in the community, about participation in the community practice. A novice is not simply a person who lacks some entities called 'skills' but rather a newcomer who needs to negotiate her or his participation in the community practice (Wenger, 1998). A person engages in ongoing negotiation of membership/participation in different communities of practice. Learning, as a process of negotiation and renegotiation of participation in the community of practice, is often not prime-time community business; rather it is always going on in the periphery of community activity. Because the community is aware of newcomers, the peripheral processes of negotiation and renegotiation of participation have a legitimate character. Newcomers are anticipated and usually (but not always!) organized by the community. An analysis of situated learning allows Lave and Wenger to construct a new productive concept of 'legitimate peripheral participation' that becomes the main definition of learning and development.

Learning as a communal process is both a descriptive and guiding approach (Matusov et al., 2007b). A view of learning as communal processes embedded in communal practices has inspired many educational practitioners and researchers to explore and define new conceptual and empirical forms of guidance that can be used in schools such as *instructional conversations* (Tharp and Gallimore, 1988), *reciprocal teaching* (Brown and Palincsar, 1987), *cognitive apprenticeship* (Rogoff, 1990), *community of learners* (Brown and Campione, 1994; Matusov et al., 2012; Rogoff et al., 1996), *practice- and problem-based learning* (Gijselaers, 1996), *building a professional community* (Matusov et al., 2005), *dialogic inquiry* (Wells, 1999), *dialogic pedagogy* (Matusov, 2009; Sidorkin, 1999; Wegerif, 2007), and *authorial teaching and learning* (Matusov, 2011a). This family of instructional approaches and models shares at least the following important principles: learning is a communal process, learning is embedded in activities and practices in which it occurs, learning involves development and negotiation of new communal identities, students' guided initiation of discourse and definition of problems and goals are crucial for becoming an active member of a community of practice, ownership for guidance and learning should be shared among students and between the students and the teacher, and a community is based on practice and communication. Nonschool sociocultural research on learning shares many of the same principles (Cole, 1996; Heath, 1994; Wenger, 1998).

Finally, influenced by another Soviet scholar Mikhail M. Bakhtin (1896–1975), a philosopher and literary theoretician of the dialogic framework, there have been increasing doubts that the purpose of development and education is in the elimination of gaps between less and more capable people, as Vygotsky seemed to imply in his notion of ZPD. Bakhtin argued that elimination of gaps between consciousnesses is both impossible and undesirable (Bakhtin, 1986, 1999). Matusov (2011b) has come to a conclusion that the important and irreconcilable difference between Vygotsky and Bakhtin comes from their different assumptions about the nature of human consciousness. Vygotsky treated consciousnesses as potentially transparent to each other, while Bakhtin treated consciousnesses as essentially opaque to each other.

Toward What Does the Development Go?

According to Vygotsky, development leads toward a buildup of higher mental functions with mediated cognition increasingly playing the central role among all other psychological functions that promote self-regulation in the individual. Vygotsky's primary focus in his *cultural-historical theory* of development was on how human society reproduces itself. Vygotsky often saw non-Western cultures as 'historical slices' of the past development of Western civilization (Luria, 1976; Vygotsky and Luria, 1993). When the developmental directionality was considered, Vygotsky was, at least, inconsistent with his own tenet that stressed the contextual and activity specificity of intellectual functioning (Cole, 1988; Scribner, 1977). Prioritizing self-regulation, mastery of independent working, literacy, schooling, scientific concepts, universal rationality, decontextualization, universality in societal development, and systematic hierarchical thinking as the pinnacle of individual's development reveals Vygotsky's ethnocentrism (Matusov, 1998, 2011b; Matusov and Hayes, 2000; Rogoff, 1990; van der Veer and Valsiner, 1991; Wertsch, 1985).

A diversity of goals of different cultural communities necessitates defining development in terms of progress toward more responsible participation in specific communities of practice rather than assuming that development is a generic and universal process independent of the goals and institutions of the communities in which an individual develops. As Tharp and Gallimore (1988) argue, "Boys in Micronesia, where sailing a canoe is a fundamental skill, will have a ZPD for the skills of navigation, created in interaction with the sailing masters. A girl in the Navajo weaving community will have experiences in a zone not quite like any ever encountered by the daughters of Philadelphia" (p. 31). At the same time, the developing individual contributes to the further development of the practices (and goals and institutions) of the community.

Griffin and Cole (1984) argue that the ZPD is not only about a gap between the child's present and the adult's past but also between the child's present and the society's future. They criticized the conservative and reproductive nature of learning and development assumed in both Vygotsky's notion of ZPD and Bruner's notion of scaffolding. These authors argue that development and education is "a dialogue between the child and his [unknown – EM] future; [it should not be – EM] […] a dialogue between the child and an adult's [known – EM] past" (Griffin and Cole, 1984: p. 62). There is an increasing tendency in the social sciences to consider the developmental telos as a social construction (Gergen, 1994) and dialogic negotiation (Matusov et al., 2007a) of cultural, institutional, communal, and personal values that have both stable and dynamic components that can conflict with each other

(Lemke, 1995). The historical time when positive values of literacy, school, science, rationality, intelligence, and the Western civilization were unquestionable in the social sciences is gone. Stemming from Vygotsky's cultural-historical theory, new approaches to development and learning are emerging. There has been a growing call for viewing development and education as production and active making of culture, rather than reproduction, focusing on human authorial agency transcending of the given (Bibler, 2009; Lobok, 2012; Matusov, 2011a).

Vygotsky's Theory of Cognitive Development

Alex Kozulin, Feuerstein Institute, Jerusalem, Israel

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Vygotsky's theory of cognitive development is recognized as one of the most innovative psychological theories of the twentieth century. The theory is based on the assumption that culture plays a major role in cognitive development. Each period in child development is associated with a leading activity dominant in a given period. A considerable emphasis is placed on emergent cognitive functions conceptualized through the notion of the zone of proximal development. Instruction and learning are perceived as leading child's cognitive development rather than following it.

History

With wisdom of hindsight, Vygotsky's theory (VT) of cognitive development should be recognized as one of the most innovative psychological and learning theories of the twentieth century. Lev Vygotsky (1896–1934) lived a short but intellectually very intensive life in a period of war, revolution, and social upheaval in Russia. His early interests were in the field of art and literature, and he earned a PhD for his theoretical work on the psychology of art. This interest in art and humanities rather than sciences may explain Vygotsky's conceptualization of psychology as a cultural, rather than natural science. He was able to devote only 10 years (1924–34) to systematic research leading to his theory of cognitive development. Two years after his death of tuberculosis, VT together with other works in the field of applied child psychology (called 'pedology' at that time) became blacklisted by the Soviet government (Kozulin, 1990; Van der Veer and Valsiner, 1991). Only in the late 1950s was the ban lifted and Vygotsky's papers reprinted in Russia. Though some articles by Vygotsky and his colleagues, Alexander Luria and Alexei Leontiev, were published in English in the 1930s, it appears that VT made practically no impact on theories of cognitive development popular in the West at that time. The first book-length publication of Vygotsky's work in English came out in 1962 as an abridged version of *Thought and Language* (later expanded, see Vygotsky, 1934/2012). It was followed by several other translations, culminating in the six-volume set of Vygotsky's *Collected Works* (1987–98). Instead of fading VT became more and more popular with the passage of time. One possible reason is that this growing popularity is associated with the fact that VT provides some tentative answers to the questions that Western psychology and education started asking only recently. At the same time, the development and popularization of VT was seriously complicated by the early demise of its author. We will never know what Vygotsky would have said about translations, interpretations, and further developments of his theory; the author's voice is very much missing in the dialogue on VT.

In what follows, five major aspects of VT will be reviewed together with their educational applications: the sociocultural orientation of VT, the concept of mediation, periods of child development, the relationships between language and thought, and the concept of the zone of proximal development (ZPD).

Sociocultural Orientation

The distinctive feature of VT is its emphasis on culture as the most important factor of cognitive development. Though Vygotsky readily admitted that some basic cognitive processes can be shared by humans and higher animals, he explicitly and deliberately focused his own theory on those cognitive processes that are uniquely human. He called them 'higher mental processes' and associated their development with the involvement of cultural tools in the shaping of human cognition. Culture in VT is not an external envelope or ethnographically specific appearance of human behavior and thinking; culture according to VT is the force that shapes all higher mental processes, such as perception, attention, memory, and problem solving. In the absence of more appropriate terms, we still use the same verbal labels for both basic cognitive processes and culturally shaped higher mental processes though these two groups of processes are very different in their origin, development, and capacity.

Taken as a whole, the VT posed three major objectives for a study of human psychology: reconstruction of the transition from an animal to a human way of thinking and behaving; investigation of the historical change occurring in human mental functions as a result of the introduction of new cultural tools and sociocultural activities; and investigation of the developmental construction of children's and adults' psychological functions in a given society (Vygotsky and Luria, 1930/1993).

Regarding the first objective, Vygotsky relied mainly on the comparison of human behavior and the behavior of apes as reported by other researchers, such as Wolfgang Kohler (see Vygotsky, 1934/2012: pp. 73–85). Vygotsky suggested that nonhuman primates have both some intellectual problem-solving skills and communicative abilities, but that in the apes these two domains remain dissociated. Communicative abilities do not impact on problem solving, while problem solving does not shape interpersonal interaction. In a human child, intensive interaction between these two domains takes place during the second year of life. As a result, speech becomes intellectual, while problem solving acquires the quality of verbal intelligence. Thus, the transition from animal to human cognition was envisaged by Vygotsky as a change in the interaction between different cognitive functions. Vygotsky and his colleagues, however, had no opportunity to investigate this hypothesis in

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23094-8

actual studies with nonhuman primates. The development of Vygotsky's line of reasoning can, however, be identified in the work of Tomasello (1999) and his colleagues. First Tomasello (1999: p. 48) reasserts the main thesis of VT regarding the cultural origin of human higher metal processes: "Following Vygotsky and many other cultural psychologists, I contend that many of the most interesting and important human cognitive achievements, such as language and mathematics, require historical time and process for their realization – even if most cognitive scientists largely ignore these historical processes." He then proceeds to show that in a number of cognitive tasks such as spatial memory, rotation of objects, and estimation of quantities, chimpanzees demonstrate performance comparable to and sometimes exceeding that of two-and-a-half year old children. At the same time children have an obvious advantage in the tasks related to gestural communication, observational learning, and understanding of intentions. Tomasello (1999: p. 213) concludes his analysis by stating that: "Language does not create new cognitive processes out of nothing, of course, but when children interact with other persons intersubjectively and adopt their communicative conventions, this social process creates a new form of cognitive representation – one that has no counterpart in other animal species."

Vygotsky should also be credited with posing an intriguing question regarding possible historical changes in human cognition. Are cognitive functions of people in antiquity, Middle Ages, and the eighteenth century the same as those of people in the twenty-first century? Do the historical changes in cultural tools impact on our cognition? In the absence of a 'time machine,' Vygotsky and Luria decided to rely on a 'quasihistorical' study of cognition in a traditional society that undergoes rapid sociocultural change. Vygotsky and Luria thought that they had found such a historical 'experiment' in the Soviet Central Asia of the early 1930s. The unique sociocultural situation of this region in the late 1920s and early 1930s was determined by a very rapid invasion of Soviet power into an otherwise traditional and mostly nonliterate agricultural society. As a result, people belonging to the same economic and sociocultural group, often even to the same extended family, found themselves under very different sociocultural circumstances. Some of them, especially those in the remote villages, retained all aspects of a traditional nonliterate culture and way of life. Others became involved in new agricultural or industrial enterprises, exposed to the new technology and means of communication, but still without access to systematic formal education. Some of the local people, however, already attended adult literacy courses and even teachers' colleges.

The main conclusions reached by Vygotsky and Luria on the basis of this study were that informants who retain a traditional nonliterate culture and way of life tend to solve problems by using functional reasoning reflecting their everyday life practical experience and reject the possibility of looking at classification, generalization, or drawing conclusions from another; for example, more abstractive point of view. Exposure to modern technology and involvement in jobs based on division of labor tend to increase the subjects' readiness to solve problems both in functional and in verbal–logical ways. It was observed, however, that informants who did not experience formal education rather easily reverted to purely functional reasoning. At the same time, informants who received some form of formal education demonstrated a clear preference for the verbal-logical form of problem solving.

Though the goal of Vygotsky and Luria was to investigate the 'historical' change in human cognition, their Central Asia research is usually interpreted as one of the first cross-cultural studies of cognitive processes. With the wisdom of hindsight, one can distinguish a number of questions that remained unanswered in this initial research. Vygotsky and Luria seem to have grouped together different sociocultural factors such as the acquisition of literacy, formal classroom learning, exposure to modern technology, and participation in labor activities based on the formal division of labor. Each of these factors seems, however, to have a different impact on the construction of cognitive functions and should be investigated separately.

The Central Asia study later inspired the Scribner and Cole (1981) research in Western Africa that demonstrated that literacy and schooling may have a differential cognitive impact. By conducting their research in an African society where literacy in three different languages was associated with different acquisition and application contexts (school, home, and religious institution), Scribner and Cole showed that literacy does not have an overall impact on problem solving but affects specific cognitive functions corresponding to each one of the contexts. Formal education on the other hand has an impact on problem solving in the tasks that resemble those used in school. The emergence of cognitive functions was thus linked to more specific sociocultural contexts and activities. More recent studies conducted in Central American Mayan villages were able to identify the transition from subsistence and agriculture to wage economy and commerce as the main factor leading children from more concrete to more abstractive cognitive representations. At the same time, in more complex tasks that required selecting a strategy for continuation of the model pattern, schooling proved to have the strongest relationship with the choice of a more abstractive and less imitative strategy, with the involvement in the 'new' economy coming second.

Mediation: Physical, Symbolic, and Human

One of the main concepts of VT is that of mediation. Vygotsky and Luria (1930/1993) distinguished three main classes of mediators relevant for the development of cognitive functions: physical tools, symbolic tools, and human mediation. Physical tools (hammer, plow, bulldozer) aim at creating a change in the environment, and, in this sense, they 'address' external natural objects. Each physical tool, however, has a 'handle' corresponding to the physical and mental requirements of a person who operates this tool. Vygotsky hypothesized that the change in physical tools may have a reciprocal effect on the human mental functions required for 'handling' new tools. For a long time, this aspect of VT reasoning received relatively little attention; it is only recently that it has started being investigated in the context of ergonomics and the psychology of human–machine interactions.

The main emphasis of VT is on symbolic tools and their internalization in the form of inner psychological tools. Through acquisition and internalization of symbolic tools, human beings start regulating and shaping their own cognitive and behavioral processes. Child development, according to VT, can be interpreted as the gradual acquisition by the child of increasingly more sophisticated symbolic tools, such as oral speech, reading and writing systems, mathematical symbols, graphic organizers, and pictorial representations. These tools then become internalized and shape the child's cognitive processes. Each culture or subculture has its own system of symbolic artifacts. If a specific tool, for example technical drawing, is unavailable in a given cultural community its members will solve the same problem in an alternative way and their cognitive function of representation will be shaped by these alternative methods rather than psychological tools associated with internalized technical drawing. The availability of a certain symbolic artifact in a given culture, however, does not guarantee its appropriation as a cognitive tool. For example, many graphic-symbolic organizers such as tables, graphs, and charts are perceived by students as external artifacts and are never transformed into their inner psychological tools.

The concept of psychological tools helps to elucidate the distinction made in VT between basic and higher mental processes. For example, the task of recalling the positions of objects on a given surface can be achieved via a basic process of direct memorization and retrieval. However, if objects are placed on a grid-like surface, one can use a culturally developed function of 'mapping' the position of an object with the help of the rows and columns of the grid. Moreover, even when the surface does not have the features of the grid, a person can imagine and project such an imaginary grid on the surface to facilitate the memorization and recall task. While direct memorization relies on a basic cognitive process, the use of an actual or imaginary grid turns the process of memorization into a higher mental activity mediated by a psychological tool. Educational programs based on VT consider acquisition and internalization of a broad range of symbolic tools as an important objective of school education. Moreover, many cognitive education and thinking skills programs developed without the direct influence of VT aim specifically at enriching the range of psychological tools available to children (Kozulin, 1998, Chapter 4).

Regarding human mediation, Vygotsky mentioned two aspects. On the one hand he suggested that every higher mental function in the child's development first appears in the interaction between people (interpsychologically), and then, when internalized, it appears as an inner mental function (intrapsychologically). As an illustration, Vygotsky cited the phenomenon originally described by J.M. Baldwin and then by J. Piaget, namely that a child's cognitive ability to consider different points of view originated in actual arguments between children. The other aspect of human mediation mentioned by Vygotsky is the role of parents and other mentors as mediators of meaning to the children. He illustrated this by describing the evolution of the child's indicatory gesture. Such a gesture, according to Vygotsky, first appears as an attempt of the child to actually grasp some remote object. Adults who witness the child's attempt interpret it as a gesture and help the child to get the object. They thus provide a new meaning to the child's grasping movement. The child then 'accepts' this interpretation, and starts addressing his/her gesture to an adult rather than a desired object. Later on children transform this gesture into a verbal request and then internalize it in a form of command to themselves.

The role of parents and other mentors as mediators was further elaborated by R. Feuerstein (see Kozulin, 1998, Chapter 3). Feuerstein identified specific parameters that turn the situation of interaction between an adult and a child into a situation of mediated learning. By using these parameters, Feuerstein was able to identify the lack of proper mediation during childhood as a source of learning and cognitive problems later in the child's life. The consequences of the lack of human mediation, however, are not irreversible. In a number of case studies, Feuerstein and his colleagues demonstrated how intensive human mediation in late childhood and adolescence may compensate for its lack in earlier childhood.

Periods of Child Development

Vygotsky and his followers in Russia, particularly Daniel Elkonin, created an original model of the periods of child development built around the concept of so-called leading activity (Karpov, 2005). This model assumes that though children are involved in different types of activities, in each period there is one activity that plays the leading role and is crucial for propelling the child's cognitive and emotional development. The above model is explicitly culture-specific and describes periods of child development in a modern industrial society that has a formal educational system. Leading activities and developmental periods in nonliterate and nonindustrial societies and communities could be different.

The periods of child development alternate between those where leading activity has an emotional-interpersonal focus and the periods with cognitive focus. It is important to remember that these are developmental, rather than age periods: some children may stay longer in some of the periods or make a quicker transition to the next period depending on their social situation of development. Thus the ages provided in Figure 1 are approximate and should not be considered as reflecting normative data.

Age (years)	Emotional-interpersonal focus	Cognitive focus
0–1	Emotional interaction with caregivers	
2–3		Object-centered joint activity
3–6	Sociodramatic play	
6–12		Formal learning
12–18	Interaction with peers	
18+		Vocational activity

Figure 1 Periods of child development.

Within each one of the periods, the development of the child's cognitive and interpersonal skills leads to the formation of a new motive that corresponds to the new leading activity in the next developmental period. Thus, for example, the emotional component is central during the earliest period in child development, while the manipulation with objects (toys) plays a subdominant role. Gradually, however, the object-centered joint activity with adults becomes a new motive of the child and at a certain moment assumes the role of the leading activity with emotional contact becoming subdominant. In a similar way, the leading activity of object-centered play gradually prepares the child for the transition to sociodramatic play: If in the first of these two periods manipulation with a toy car is focal, in the second period the imaginary role of a driver becomes the main interest of the child.

Relative to other developmental periods, the period of sociodramatic play and the period of formal learning activity received the major attention in the VT (Karpov, 2005). There are some practical reasons for this emphasis because the period of sociodramatic play is associated with children's school readiness, while the period of formal learning is associated with education in primary schools. In the VT, school readiness is associated with the following abilities developed via sociodramatic play: the ability to flexibly switch roles, enhanced self-regulation, and the development of symbolic thought. To be ready for formal learning in school the child should be able to assume a new role of a student which is different from those of son, daughter, sibling, or playmate. Play according to specific rules enhances self-regulation, while imaginative play strengthens hypothetical reasoning. In what concerns the period of formal learning, the main contribution of VT is in distinguishing between generic learning activity that may appear as an element of play, practical activity, interpersonal interaction, and so on, and a specially designed activity of formal learning that aims at turning a child into a self-regulated learner. The true target of this leading activity is the child himself/herself, who through acquisition of reflective and metacognitive skills becomes an agent of his/her own learning. To be an agent of one's own learning does not mean, however, to learn independently; one of the main goals of primary education according to VT is to teach children how to distinguish between those elements that they can learn themselves and those aspects that require the assistance of teachers and other mentors. In other words, primary school students should be able to distinguish between what they 'know and can do themselves' and what they 'can do only with the help of others.' An elaborate request for assistance is one of the main subjects of this educational approach that will be discussed in greater detail in the last section.

Language and Thought

Among the contributions made by VT to the study of language and thought probably the most important is the broadening of the scope of what is called 'child language.' When Vygotsky and Piaget started their theoretical dialogue child language was considered almost exclusively in its communicative aspect while a child's verbal reasoning was perceived as an 'incomplete' adult thought (see Vygotsky, 1934/2012). VT radically broadened this field by focusing on such phenomena as private speech, silent inner speech, and a child's written language (Wertsch, 1985). An important role here is played by a study of child speech that apparently is not directed at any listener, and which Piaget called 'egocentric.' Piaget considered such a speech to be a by-product of a child's immature egocentric thought. The destiny of the 'egocentric' speech in his opinion was to be replaced by 'socialized' speech attuned to the expectations of the listener. Vygotsky, however, interpreted such private speech as an important developmental tool leading a child toward self-regulation and voiceless verbal thinking.

More recent studies have proved that private speech has many varieties and functions (Winsler et al., 2009). For example, many children at the age of one to three systematically engage in the so-called crib speech. Crib speech takes place at bedtime when toddlers are left in their own room and parents are either not present or at least are not visible to a child. Crib speech includes retelling significant episodes of the child's experience, questions and answers, word play, and 'experimentation' with different language forms. So instead of being a by-product of the child's immaturity, crib speech proved to be an important mechanism for the consolidation of the child's experience, language practice, and acquisition of such social communication forms as dialogue. Crib speech is often much richer than the daytime communicative speech of the same child, and as such provides a glimpse into the child's future development.

Probably the most prominent and well-researched function of private speech is its support of the child's self-regulation and problem solving (Winsler et al., 2009). It has been established that the amount of private speech in 5–7-year-old children is dependent on the subjective difficulty of the task. When the task is too easy or too difficult for a child, the amount of private speech is low. However, when the task is within the child's ZPD the amount of private speech is high. Moreover, the presence of task-relevant private speech is indicative of the child's performance not only with the present but also with future tasks. First graders who made self-guiding task-relevant comments did better at math in the second grade. While private speech is important for problem solving, one expects it to be eventually internalized; i.e., become completely silent inner speech. Children who progressed more rapidly from private to inner speech also showed better sustained attention and were less distractible. Contrarily, children who have learning problems often display private speech that is not task-related (chanting, repetitions, nonguiding comments) for a longer developmental period than children without learning problems. What started as Vygotsky's response to Piaget's notion of 'egocentric' speech has now developed into a broad area of studies on the relationship between different forms of verbalization and the cognitive processes involved in executive functions, self-regulation, and problem solving.

Another important area of research triggered by Vygotsky's critical analysis of Piaget was the distinction between everyday and academic concepts. Vygotsky (1934/2012) suggested that there is a significant difference, even conflict between spontaneous concepts that children acquire through their everyday life experience (e.g., 'The sun rises in the morning') and the corresponding academic concepts essential for

scientific and technological reasoning ('What appears as a sunrise is the result of the rotation of the Earth around its axis'). What is acceptable for everyday functioning cannot serve as a basis for rigorous academic reasoning. Vygotsky and his followers alerted educators to the fact that children do not come to the classroom as a *tabula rasa* but bring with them their preexistent everyday concepts. These concepts in themselves, however, do not lead to proper scientific reasoning. Moreover, they are the basis of many of the students' 'misconceptions' that greatly complicate math and science instruction. The acquisition of academic concepts would not happen without deliberate instructional activity. Such activity should be carried out in a 'dialogue' between the teacher's systemically organized academic concepts and the students' experientially rich but often scientifically invalid spontaneous concepts.

ZPD and Dynamic Assessment

There is little doubt that ZPD became the most popular of Vygotsky's concepts, often to such an extent that in the public mind the entire VT just becomes the theory of ZPD. Quite often, however, the popularity of ZPD fails to be accompanied by a sufficiently deep understanding of this notion. One of the difficulties in 'decoding' the notion of ZPD and its relationship to such practical application as dynamic assessment stems from the fact that Vygotsky and his followers in Russia refer to ZPD in three different contexts – developmental, educational, and directly related to assessment. In the developmental context, ZPD appears as a principle that helps to explain the dynamics of child development. Vygotsky (1935/2011) argued that typical psychological study focuses only on those psychological functions that have already fully matured and as such are displayed by children in their independent activity. What is needed is the method of evaluation of those emergent psychological functions that are still 'invisible' because children cannot yet demonstrate them without assistance. VT stipulates that in joint activity with adults these functions, however, become 'visible' and can thus be studied. The notion of ZPD allows one to see not only the developmental 'present' but also the future of the child.

In the educational context, ZPD helps to explain the relationships between education and child development. Educational process according to VT should include the development of children's cognitive functions as one of its main objectives. Contrary to a popular view that instruction should be based on already fully formed cognitive functions, VT claimed that it should target those emergent functions that can be shaped by education. In this way, students will not only acquire information and specific skills but also form higher mental functions (Kozulin et al., 2003).

In relation to assessment, ZPD was operationalized as a difference between the independent performance of students and their performance under conditions of joint activity with their mentors. In this context ZPD emerges as a precursor of what today is called dynamic assessment (Haywood and Lidz, 2007). Vygotsky (1935/2011) suggested a range of means for turning the assessment process from strictly independent into assisted: presenting a complete problem-solving model, asking leading questions, starting solutions, and then asking the child to continue. What Vygotsky did not provide was a specific step-by-step manual for conducting ZPD assessment. So his contribution in this field remained paradigmatic rather than methodological.

There is still no consensus regarding practical applications of the notion of ZPD. Some authors emphasize the developmental aspect and insist on applying the concept of ZPD only to the qualitative cognitive changes that occur in the transition from one developmental period to the next one. Other authors focus on the assessment context and argue that ZPD is useful for explaining quantitative difference between children's cognitive performance and their learning potential or the degree of their cognitive modifiability (Kozulin et al., 2003).

Taking into account the current popularization of the notion of ZPD it seems important to delineate the theoretical boundaries of this concept. Not every situation that involves a mentor, a child, and a task is related to ZPD, but only those situations that reveal or promote the development of children's psychological functions. A mere transmission of content knowledge or specific skills has nothing to do with ZPD. It would be counterproductive to apply the notion of ZPD to a situation of a teacher simply helping students with specific math or reading problem without setting any cognitive-developmental goals for this activity.

The relationship between the notion of ZPD and the current practice of dynamic assessment is far from unequivocal. Not all dynamic assessment approaches are based on ZPD, and on the other hand, ZPD is not just a theory of assessment. Today various dynamic assessment tests offer a range of possible evaluation formats from intensive one-on-one learning sessions in which the mentor flexibly reacts to the student's performance to learning sequences that are tightly scripted – standardized cues or prompts appear in response to specific answers of the student (Haywood and Lidz, 2007). There is also a variety of tasks used in dynamic assessment; some of them resemble the tasks of standard intelligence tests such as matrices, number series, and analogies, while others use curricular language and math problems. What unites all these approaches and what brings them close to VT's original vision is the need to reach beyond current problem-solving performance into the processes that lead to students' development and change.

Educational Applications

Though some of Vygotsky's ideas have been applied in clinical areas (see Kozulin, 1990, Chapter 6), the main area of VT applications is educational. These applications range from those using a general VT philosophy to specially designed educational programs with their own VT-based curriculum and didactics. Some of the former are only loosely connected to VT theory and just assert the need of taking students' culture into account or focusing not only on current achievement but also on potential. The more structured of VT-based programs and curricula usually implement some of the theoretical concepts that were discussed earlier in this article: the concept of leading activity; internalization of symbolic tools as inner psychological tools; the difference between everyday and

academic concepts; and ZPD as a basis for both assessment and educational action.

For children at kindergarten age, the leading activity is that of sociodramatic play. The VT research identified the following outcomes of this leading activity that contribute significantly to school readiness: development of the function of symbolization both in the verbal and nonverbal sphere that serves as a prerequisite for the acquisition of literacy and other symbolic systems used in school; flexible change of social play roles that helps children to accept their new role as students and reduces their cognitive 'egocentrism'; play by rules develops self-regulation and self-control essential for classroom activities (Karpov, 2005). School readiness is thus interpreted as a development of a broad range of cognitive functions and motives, rather than specific school-related skills. The preschool programs based on the VT model have been developed both in Russia and other countries (Bodrova and Leong, 2007) and have proved to be successful in enhancing children's school readiness and improving their executive cognitive functions.

Probably the best known educational application of VT is the primary school curriculum developed by Vygotskian scholars and practitioners in Russia (Davydov, 2011). The curriculum and its didactics is based on the assumption that children of a primary school age are particularly sensitive to formal learning as a leading activity. The main emphasis is put on the development of students' self-reflection and metacognition using a wide range of symbolic tools. For example, the VT-based math curriculum in the early grades focuses more on general cognitive strategies and skills rather than numerical operations. Numbers are introduced as one of the possible ways to represent the relationships between a selected 'measure' and an object of measurement rather than the operation of counting objects. Various symbolic representations and elements of algebra are introduced much earlier than in other curricular systems. Research has confirmed that students who studied math in primary school according to Davydov's curriculum performed much better with more complex PISA tasks than their peers from elite schools that used a more traditional curriculum (Zuckerman, 2004). The English version of Davydov's math curriculum was also used in a number of schools in the United States (see Kozulin et al., 2003, Chapter 12).

Even greater emphasis on symbolic tools can be seen in the program developed by Kinard and Kozulin (2008) for teaching mathematics in socioculturally heterogeneous classrooms. The authors argued that much of the students' failure in mathematics stems not from a lack of mathematical knowledge, but from underdevelopment of general cognitive skills on the one hand, and insufficient emphasis on mathematical conceptual reasoning, on the other. Their program aims at developing students' cognitive functions and problem-solving skills through appropriation and internalization first of general and then of mathematically specific symbolic tools. Codes, tables, and diagrams are examples of general symbolic tools, while number line, formulae, and coordinate system are mathematically specific tools. This is achieved by the inclusion of special cognitive tasks into the mathematics curriculum and by emphasizing the instrumental role of such mathematical tools as graphs and formulae.

VT curricula also emphasize the difference between everyday and academic concepts. Instead of trying to enrich students' preexistent spontaneous concepts, these curricula aim at developing theoretical concepts that in many respects are opposite to the notions spontaneously formed by students (Davydov, 2011). What unites all curricula based on VT is their emphasis on education as an 'engine' of students' cognitive development. Instead of perceiving the curriculum as an informational content that should be given to students who already have all the prerequisite cognitive functions, the VT-based curriculum aims at actually forming these functions.

The educational application of the concept of ZPD includes a closer integration of assessment and learning processes. Typical educational intervention based on the VT model starts with the evaluation of students' performance in a target learning area (e.g., proportional relationships): some students in a given classroom demonstrate that they have already mastered these relationships, some that they are within their ZPD, and others that they are still beyond their ZPD. This initial evaluation helps to formulate the instructional strategy for students belonging to the three subgroups. After a certain period of intervention, the evaluation is repeated and the cycle of assessment and instructions continues (Zuckerman, 2004). In some respects, this approach has a certain affinity with 'formative assessment,' though the latter usually focuses on curricular content and skills rather than on students' cognitive development.

Theoretical Impact of VT

The continuing and ever growing interest in VT might be related to the fact that one can find in it some tentative answers to the questions that emerged in psychological and educational theory only recently. Through its notion of psychological tools, VT helps to operationalize cognitive differences observed in multicultural classrooms. The distinction between everyday and academic concepts allows us to better understand students' 'misconceptions' and explains the lack of success of educational approaches built around children's everyday experiences. The notion of ZPD has not only paved the way for dynamic assessment but has also helped to turn cognitive development into one of the objectives embedded into almost every one of the national curricula. At the same time, the potential of VT is far from exhausted; many of the VT-based educational applications still remain at the pilot stage awaiting more comprehensive research, development, and implementation.

Vygotsky's Sociocultural Theory

Natalia Gajdamaschko, Simon Fraser University, Vancouver, BC, Canada

Abstract

Lev Vygotsky created a theory of psychological development that has become increasingly influential in recent decades. The theory is viewed by some psychologists and pedagogues as alternative way to understand the development of children and adults in a way that differs substantially from the dominant psychological models that have long been widely accepted, including Piaget.

Vygotskian psychology includes many important concepts that are not found in, or at last are not central to, other psychological theories. Among the most important concepts are (1) the existence of higher psychological functions that differ from lower psychological functions, (2) the mediated nature of higher psychological functions, (3) the existence of internal and external tools that transform the structure of mental function, (4) the central importance of culture and history, as a process of becoming, in development, (5) zone of proximal development.

Overview of Vygotsky's Education and Career

Lev Semenovich Vygotsky was born in the town of Orsha, Vitebskaya Oblast (former Mogilevskaya Gubernya), Belorussia on 5 November 1896 and grew up in Gomel, a larger Belorussian city about 150 miles from his birthplace. There as a young child, he was homeschooled by his father, Semen L'vovich, a banker, and his mother, Cecilia, a teacher by training, plus some tutors hired to assist them. After 5 years of schooling at home, he attended a private single-sex secondary school. As a gifted student, he excelled in all subjects, but was particularly interested in literature and philosophy, subjects for which he maintained an intense interest throughout his life. According to Gita Lvovna Vygodskaya (1925–2010), his daughter and biographer who meticulously cataloged his early life and family history, Lev Vygotsky's interest in arts and humanities was due mainly to the influence of his family, one of the best educated in Gomel.

He graduated in 1913 from secondary school with the highest honors, but his hopes to study philology, his favorite subject, at a university and to become a public school teacher were dashed on the rocks of Tsarist Russia's anti-Semitism. Such a path was not open to Jews in prerevolutionary Russia. Instead, heeding the advice of his parents, Vygotsky decided to study medicine, a more practical profession: As a medical doctor, he could choose to live outside the pale, the boundaries of Jewish settlements in Tsarist Russia. He was admitted to the medical school of Moscow University, but after only a month studying medicine, he transferred to the school of law. A year later, in 1914, while continuing to study law, he, because of his deep interest in literature, art, and philosophy, enrolled in the history-philosophy department of Shanyavsky University. Soon after that, he added psychology to his course of study there.

Vygotsky's first paper, written during his student years, addressed problems of literary criticism. A student graduation paper was titled, 'The Tragedy of Hamlet, Prince of Denmark.' Though not published at the time it was written, it was rediscovered and published 52 years later as a part of second edition of *The Psychology of Art*, in 1968. According to Gita Vygodskaya, the essay was recognized for its originality and unique analysis of Hamlet (Vygodskaya and Lifanova, 1996).

In 1917, Vygotsky graduated from the two Moscow universities and moved back to Gomel to join his family, which had not been spared the harsh impacts of World War I and which would suffer more hardships during the Great October Socialist Revolution and the subsequent civil war. During these times, two of his brothers died.

Though this period of Vygotsky's life is often overlooked by researchers, according to Gita Vygodskaya (1996) Vygodskaya and Lifanova, 1996, the 7 years Vygotsky spent in Gomel after he returned in 1917 were important for his professional and personal development. During this time, he taught at the local pedagogical college, managed a theater, and published a journal of literary criticism. Most importantly, he created his first laboratory in Gomel and began serious study of the psychology of art and the psychology of education. This work led directly to his first major book on psychology, *The Psychology of Art*, which was completed in 1925, but first published in 1965. A second book, *Pedagogical Psychology* was published in 1926, but was later withdrawn from libraries and banned by Communist authorities for more than 60 years. It was republished at the end of the 1980s. While Vygotsky's early writings are often difficult to reconcile with what he wrote during the decade after he left Gomel, they provide researchers with insights into his intellectual development.

In 1924, Vygotsky moved from Gomel to begin an association with the Moscow Institute of Experimental Psychology that would last until his death. He was invited to join the Institute after he made an impressive presentation at the Second Psychoneurological Congress in Leningrad. As a young, unknown researcher who had been working in obscurity far from the center of Russian intellectual life, Vygotsky's presentation so captivated future colleagues, such as Alexander Romanovich Luria, that they wanted him to join them in their work (Cole et al., 2005: p. 39).

At the Institute, Vygotsky, together with his close friends and colleagues Luria and Aleksei Nikolaevich Leont'ev, set out to build a new approach to the study of human development. Their goal was to help create a Soviet psychology by revising and reforming psychology along Marxist lines and building a new, objective materialistic approach to psychology. Their work was influenced by the profound social changes that

followed the Communist revolution, which created a new context for their research. They sought to address the practical needs of the newly formed educational, clinical, and academic systems in the Soviet Union.

As he began his work at the Institute, Vygotsky believed that psychology was in a crisis, divided into two camps that represented different scientific schools that had little interest in mutual understanding. One camp was objective psychology, built on the principles of natural sciences. The leading Russian members of this school were I. M. Sechenov and Ivan Pavlov, who studied reflexes. The second camp included psychologists with phenomenological, idealistic, and subjective orientations.

In response to this perceived crisis, Vygotsky, already ill with the tuberculosis that would kill him, wrote while in a hospital *The Historical Meaning of the Crisis in Psychology*, an attempt to unite the mutually contradictory objective and subjective schools of thought. Although the book was finished in 1927, its publication was not allowed by the Soviet government until 1982. Despite his inability to get the book published, Vygotsky and his colleagues widely spread the ideas in it through their lectures and papers, and his theoretical analysis led to the development of the cultural–historical theory of human development. The elements of this theory are set out in more than 270 articles, book, and monographs he published between 1924 and 1934, the year of his death.

This decade of feverish activity was greatly affected by two developments: the rise of Stalinism and Vygotsky's terminal illness. The increasingly repressive political climate in Moscow caused Vygotsky and his colleagues to relocate to Kharkov to avoid the intense political scrutiny of communist ideologues in Moscow. As a result of the Institute's relocation, Vygotsky spent much time during his last 7 years in trains, traveling between Moscow, Kharkov, and Leningrad.

Vygotsky undertook this travel and kept such an intensive work schedule despite, or perhaps because of, the fact that he knew that tuberculosis would shorten his life. He died in 1934 at the age of 37. His death spared him from the possibility that he might be punished by the Soviet regime as were other leading intellectuals. Although it is impossible to know what would have happened to him if he had lived longer, his likely fate may be indicated by the treatment of his research: his books and papers were banned in the Soviet Union until 1956 as a result of the special decree of Central Committee of Communist Party.

Two years after Vygotsky death, the special decree of Central Committee of Communist Party was issued about pedology on 4 July 1936 (Постановление ЦК ВКП(б) О педалогический извращениях в система накромпросов) was a definitive ruling on what was considered as the orthodox, and thus only acceptable view of the Soviet authorities on the topic. Vygotsky's work was deemed heterodox and thus suffered the fate of being forbidden to be published and republished, withdrawn from libraries and partially destroyed (Vygodskaya and Lifanova, 1996).

Thanks to his family (especially his daughter Gita), colleagues, and friends, most of his written work was preserved in storage and many of his ideas were passed along orally, so that the Stalin regime was not successful in obliterating his contributions to psychology. In fact, Vygotsky is now viewed by many as one of the most influential figures of twentieth-century psychology and pedagogy. Remarkably, the books and articles he wrote more than 80 years ago continue to inspire new researchers and to influence practitioners.

The Essentials of Vygotskian Psychology

With his colleagues Luria and Leont'ev, Vygotsky created a theory of psychological development that has become increasingly influential in recent decades. The theory is viewed by some psychologists and pedagogues as alternative way to understand the development of children and adults in a way that differs substantially from the dominant psychological models that have long been widely accepted, including Piaget.

Because Vygotskian theory offers a substantially different understanding of psychological development, the theory suggests different methods of psychological research and new approaches to pedagogy. Educators who believe that Vygotskian theory accurately reflects the process of development have developed approaches to teaching that differ from those based on the traditional theories underlying pedagogy in the West.

Vygotskian psychology includes many important concepts that are not found in, or at last are not central to, other psychological theories. Among the most important concepts are (1) the existence of higher psychological functions that differ from lower psychological functions, (2) the mediated nature of higher psychological functions, (3) the existence of internal and external tools that transform the structure of mental function, (4) the central importance of culture and history, as a process of becoming, in development, (5) zone of proximal development.

These core ideas of Vygotskian theory, plus other aspects of his theory, are discussed in more detail below.

A New 'Instrumental,' 'Cultural,' and 'Historical' Approach to Psychology

According to Cole et al. (2005), Vygotsky initially liked to describe the new theory of human development is as 'instrumental,' 'cultural,' and 'historical' psychology (pp. 44–45). Each term highlighted a different feature of his new approach to psychology.

The term *instrumental* reflected a fundamental idea that higher psychological functions, that is, cultural functions, are mediated. Unlike basic functions such as reflexes that can be analyzed as simple stimulus–response interactions, cultural functions incorporate in their structure new elements – external and internal tools – that transform the whole framework of mental functioning. External and internal tools are *instruments* that individuals use to modify and master their own behavior. The analysis of these tools became an essential element of Vygotsky's new approach to understanding human development. The method of analyzing tools is known as the double-simulation method.

The different characteristics of basic or natural psychological functions and higher psychological functions are shown in **Table 1**.

The term *cultural* was used to describe Vygotsky's theory because cultural development is a unique direction in the development of a child. Cultural development is concerned

Table 1 Differences in natural psychological functions and higher psychological functions

	Natural psychological functions	*Higher psychological functions*
Origin	Genetically inherited	Socially acquired
Structure	Unmediated	Instrumental, mediated by social means
Functioning	Involuntary	Voluntarily coconstructed and controlled
Relation to other mental functions elements	Isolated	Broad system of functions, not separate

with the 'social situation of development.' It reflects the socially constructed ways that society organizes various types of tasks faced by a growing child. It also refers to the physical and mental tools that society provides to a young child to master those tasks.

Closely connected to the *cultural* aspect of Vygotsky's theory is the *historical* aspect, which is a focus on studying development in the process of change. It incorporates Hegel's dialectic concept that things are constantly changing due to the conflicts and tensions inherent in their contradictory elements. Thus, for Vygotsky, development is constant transformation: it is never stable; rather it is a continual process of becoming. This dynamic concept of history differs greatly from the understanding of history in the West. For them, to study something historically means, by definition, to study past events. Thus, they differentiate between the study of the history of behavior and the study of present-day behavior. For Vygotsky, the two are inseparable in that they are linked together in the process of change that defines development. The present state of a person's development is unknowable without knowing the history of his or her development.

Development by Changing the Interfunctional Structure of Consciousness

Indicated by the importance of the instrumental, cultural, and historical elements of Vygotsky's theory, psychological functions develop throughout childhood by the acquisition of cultural (psychological) tools created by society and by the 'process of becoming' as psychological functions are restructured within the culture. In addition, Vygotsky suggested that development comes by changing the interfunctional structure of consciousness. In this regard, he criticized models that ignore the interdependence of psychological processes and the methods designed to study only individual functions in isolation. Instead of viewing the process of development as a structural change of a single psychological function, Vygotsky suggested that psychology should investigate the changing relationships between psychological functions and their developmental changes. He wrote:

> In the process of development, it is not so much the functions which change (these we mistakenly studied before). Their structure and the system of their development remain the same. What is changed and modified are rather the relationships, the links between the functions.
>
> Vygotsky L.S 1930/1987 On psychological systems, vol. 3, p. 92

Departing from the Old Theories: Development as Cultural Development

Vygotsky's research led him to conclude that the traditional psychology of development could not handle the task of researching cultural development properly because "child psychology did not know the problem of higher mental functions or, what is the same, the problem of the cultural development of the child. For this reason, the central and greater problem of all psychology, the problem of personality and its development, still remains closed" (vol. 4, p. 26). He continued:

> Only a decisive departure beyond the methodological limits of traditional child psychology can bring us to a study of the development of that same higher mental synthesis that, on a solid basis, must be called the personality of the child. The history of cultural development of the child brings us to the history of development of personality (vol. 4, p. 26).

He concluded by observing that many psychologists still analyzed changes in behavior as resulting from changes in natural or basic psychological functions rather than changes in culture. He wrote, "[They] are inclined to … think of [changes in behavior] as facts of habit formation or as intellectual reactions directed toward cultural content" (1997b; vol. 4, p. 92).

Vygotsky's call for a broader study of a child's context stood in stark contrast to theories advocated in the West. The contrast between his own theory and Western thought is exemplified by Vygotsky in his critique of Piagetian theory. Vygotsky believed that Piaget focused too narrowly on identifying both the internal and external sources of a child's development and studying them in isolation. This approach, Vygotsky argued, relied too much on reductionism and ignored culture and history in a child's development, as well as the child itself; that is, the impact of the child's personality on the child's development. He wrote:

> What … is missing in Piaget's perspective is reality and the child's relationship to that reality. What is missing is the child's practical activity. This is fundamental. Even the socialization of the child's thinking is analyzed by Piaget outside the context of practice.
>
> Vygotsky, 1987; vol. 1, p 87

Unlike Piaget, Vygotsky placed the child at the center of his theory and accounted for the mediated nature of cultural development. In the process of development, a child will 'arm and rearm' himself with widely varying tools. Only the acquisition of cultural tools allows the transformation from lower natural functions to higher (cultural) functions:

> If we seriously consider the fact that with the knot tied for remembering, man, in essence, constructs externally a process for remembering, the external object compels him to remember, that is, he

> reminds himself through an external object, and, in this way carries out a process of remembering as if externally, converting it to external activity; if we consider the essence of what occurs here, this one fact can disclose for us all the profound uniqueness of higher forms of behavior.
>
> Vygotsky, 1997; vol. 4, p. 59

> The very essence of human memory consists of man actively remembering with the help of signs. In general, the following might be said about human behavior: in the first place, his individuality is due to the fact that man actively participates in his relationships with the environment and through the environment he himself changes his behavior, subjecting it to his control.
>
> Vygotsky, 1997; vol. 4, p. 59

Warning against a mechanical understanding of the role of 'psychological tools' in a child's activity, Vygotsky explained that not everything could be a tool. If something "did not have the capacity to influence behavior, it could not be a tool" (Vygotsky; vol. 3, p. 87). Following the Hegelian idea that cultural tools, internalized, empower a child in its development, Vygotsky considered the mediated nature of psychological functions to be one of the most important mechanisms of development. A function that a child consciously masters acquires other possibilities of action.

Another aspect of Vygotsky's views on child development that is intimately connected to understanding context in a new way is his idea of development by means of changes in psychological systems. The structural and functional characteristics of cultural functions change not only because new cultural tools are acquired, but also because they enter into a new relationship with each other at every stage of development. Applying this notion to development of different psychological functions, Vygotsky pointed out that the context of development changes because psychological functions are in a constant and ever-changing relationship during the process of a child's development. In this regard, Vygotsky wrote that one of the most fundamental idea of developmental psychology is that there can be no fixed relationship between thinking and speech, for example. As he illustrated in his volume *Thinking and Speech*, at each stage of development we observe a unique and changing set of relationship.

Extending the same idea to the evolving development of imagination, for example, Vygotsky wrote:

> Imagination does not develop all at once, but very slowly and gradually evolves from more elementary and simpler forms into more complex ones. At each stage of development it has its own expression; each stage of childhood has its own characteristic form of creation. Furthermore, it does not occupy a separate place in human behavior, but depends directly on other forms of human activity, especially accrual of experience.
>
> What is substantially new in the development of fantasy during the transitional age is contained precisely in the fact that the imagination of an adolescent enters a close connection with thinking in concepts; it is intellectualized and included in the system of intellectual activity and begins to fulfill a completely new function in the new structure of the adolescent's personality.
>
> Vygotsky, 1998; vol. 5, p. 154

This complex view of the evolving development of thinking, speech, and imagination contrasts with the belief that intellectual change during adolescence is "a simple quantitative accumulation of characteristics already laid down in the thinking of a three year old." According to Vygotsky, the word 'development' does not apply to this explanation of intellectual change (Vygotsky, 1998; vol 5, p. 29).

Vygotsky formulated the first law of the development and structure of higher mental functions, which can be called "the law of the transition from direct, innate, natural forms and methods of behavior to mediated, artificial mental functions that develop in the process of cultural development" (vol. 5, pp. 167–168). He wrote that every function in the child's cultural development appears twice: first on the social level and, later, on the individual level. This applies equally to voluntary attention, to logical memory, and to the formation of concepts. All the higher functions originate as actual relations between human individuals.

The Social Situation of Development

To help understand the dynamics of child development, Vygotsky focused on the social situation of development, by which he meant "the relations between the personality of the child and his social environment at each age level" (Vygotsky, 1998; vol. 5, p. 198). El'konin (1998 as cited in Vygotsky, 1998; vol. 5, p. 312) observed that "For Vygotsky, the central point in considering the dynamic of mental development at this or any period in the life of a child was the analysis of the social situation of development." This concept helped Vygotsky capture the unity of the context and the personality of a child as one unit of analysis.

According to Vygotsky, at the beginning of each age period, an original, exclusive, and unique relation develops between the child and reality (mainly the social reality that surrounds him). He explained, "The social situation of development represents the initial moment for all dynamic changes that occur in development during the given period. It determines wholly and complete[ly] the forms and the path along which the social becomes individual" (Vygotsky, 1998; vol. 5, p. 198).

Based on his notion of the social situation of development, Vygotsky suggested three important elements of the dialectical relationship between context and development.

1. The social situation of development is dynamic. He wrote: "The very initial and essential point in the general determination of the dynamics of age is to understand that the relations between personality of the child and his social environment at each level is mobile" (Vygotsky, 1998; vol. 5. p. 198).
2. The idea of 'crisis in development' should be used to help understand the dynamic and mobile nature of the role of context in development. Context must be treated dynamically and not statically, and Vygotsky proposed to focus on 'crisis in development' as a means to insure that the dynamic nature of context is at the center of its analysis. According to Vygotsky, even if crises of development were not discovered empirically or not noticed in practice, they should nevertheless be 'invented' theoretically.

The context of development, in Vygotsky's view, should follow the Hegelian understanding of uneven, revolutionary

development that includes some stable stages that are replaced by revolutionary jumps. Vygotsky explained the crisis dynamic as follows:

> The crisis of the newborn separates the embryonic period of development from infancy. The one-year crisis separates infancy from early childhood. The crisis at age three is a transition from early childhood to preschool age. The crisis at age seven is a link that joins pre-school and school ages. Finally, the crisis at age thirteen coincides with the turning point in development at the transition from school age to puberty …. Thus, [c]ritical periods alternate [with] stable periods and are turning points in development, once again confirming that the development of the child is a dialectical process in which transition from one stage to another is accomplished not along an evolutionary, but along a revolutionary path.
>
> Vygotsky, 1998; vol. 5, p. 193

3. Attention should be devoted to understanding the changing nature of development during both stable and critical periods of development. Vygotsky believed that following the idea that each stage of development has a unique set of characteristics, the differential study of critical and stable periods would bring us closer to understanding the nature of development. As El'konin (p. 312) wrote, "According to Vygotsky's thinking, the disintegration of the old and appearance of bases of the new social situation of development is the main content of the critical age levels." Unfortunately, this line of Vygotsky's research was not developed much by his followers.

In summary, the concept of the social situation of development helped Vygotsky capture the dynamism of context by pointing out that the social situation of development is unique for each stage of development. It also allowed him to uncover the mechanisms of development by identifying possible contradictions within the social situation of development that would bring in necessary changes in psychological systems of developing cultural function.

In this way, crises help to uncover the inner logic, the essence of development, by highlighting and bringing forward the contradictions between the personality of a child and the context of development that are their source.

Perezhivanie as a Unit of Analysis

In building his analysis, Vygotsky introduced 'perezhivanie' as the 'unit of analysis.' *Perezhivanie* can be translated as experience or experiencing.

Vygotsky advocated the studying complex *perezhivanie* as a product of cultural–historical development mediated by 'cultural tools/artifacts' that are social in origin and are interiorized/appropriated by the child within a particular cultural tradition.

Realization of the sociocultural approach in the study of *perezhivanie* presumes analysis of at least three interrelated questions: What are the specific cultural tools of *perezhivanie*? What are the specifics of the process of their appropriation by a person? What is role of other people in this appropriation and *perezhivanie* of the person? Vygotsky points out that such a study of child's relation to the context of development differs drastically from the phenomenological attempts to study of emotional experience because it is based on the different methodological principles. Perezhivanie as a unit of analysis is closely related to Vygotsky's notion of systemic and semantic structure of child's consciousness.

Vygotsky argued that in order to understand the development of a child's consciousness as a unity of communication and generalization that comes to a child through concept development. In *Thinking and Speech*, Vygotsky stressed that although the objective meaning of a concept could be the origin of conceptual development of a child, in reality, it is impossible to have direct and unmediated teaching of the objective meaning of a concept. Behind the acquisition/appropriation of the culturally given meaning, there is a whole world of personal sense that belongs to the personality of the child. It is not possible to produce directly the internalization of the meaning of the world; it can come only through the layers of mediation and a sense of the meaning in the world of the child.

Conclusion

In his tragically shortened life, Lev Vygotsky, with his colleagues, formulated a complex theory of child development that has in the past couple of decades provided an alternative to the long-prevailing models in the West, stimulated new research of core issues in child development, and inspired teachers and pedagogues in countries throughout the world to try new ways of teaching. Long after it was created, Vygotskian psychology has taken its place among the major theories of how children think and learn.

Elements of this theory have found their way into psychology and pedagogy courses taught at major universities in the Western hemisphere, and it continues to be a major intellectual influence in Russia and other countries of the former Soviet Union. A center for Vygotskian studies is located at the Vygotsky Institute, Russian State University for the Humanities, in Moscow, founded by his daughter and granddaughter, and now headed by a granddaughter, Dr Elena Kravtsova. This center holds an annual conference on research related to Vygotsky. Its Web site is http://psychology.rsuh.ru/.

In the West, several groups explore and interpret Vygotskian psychology. Most noteworthy is a circle created by Prof. Mike Cole and his Laboratory of Comparative Human Cognition at the University of California, San Diego. The group is called XMCA. It was started initially as a listserv for the discussion of Vygotskian psychology, but through the years it has become a key place for Vygotskian scholars throughout the world to collaborate and interact with each other.

In addition to XCMA, the Laboratory of Comparative Human Cognition, under Prof. Coles' leadership, also publishes a quarterly journal, *Mind, Culture, and Activity*, that is devoted largely to Vygotskian-related research. See the following Web site for more information about the Vygotskian discussion list and journal: lchc.ucsd.edu.

Another group addressing Vygotskian psychology is a Special Interest Group (SIG) of the American Education Research Association (AERA). The Vygotskian SIG meets annually at the AERA meeting, organizing different paper

sessions and roundtable discussions, plus it provides professional development opportunities for graduate students and younger faculty members. More information about this group is available at this site: http://www.aera.net/SIG030/CulturalHistoricalResearchSIG30/tabid/13234/Default.aspx.

In all, Vygotsky and his ideas have continuing credibility and influence, offering an alternative way to understand child development and to provide a means for more effective teaching. The future of his ideas depends, to a large extent, on continued research by scholars to test his theory to determine the validity and value of its key ideas.

Wage Differential and Structure

Robert Drago, Precision Numerics, Springfield, MA, USA

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by G. Johnson, volume 24, pp. 16345–16350, © 2001, Elsevier Ltd.

Abstract

This article discusses five major sources of wage differentials. These include the *skills* required by jobs, such as complexity or investments in human capital; *job location*, which can yield differences for urban as opposed to rural locations; the effects of *job characteristics*, including some jobs involving dangerous conditions; *discrimination or nepotism* related to gender, race/ethnicity or family status; and *rents* due to labor unions or governmental policies such as a minimum wage.

At a point in time in a particular economy, there will be a distribution of wage rates (average total compensation per hour) across all economically active members of the population. This distribution of wages is referred to as the wage structure of the economy. The value of the wage rate of each member of the labor force will depend systematically on a set of observable characteristics of that person as well as on other characteristics that are not observed. This relation between wages and worker characteristics, as well as the distribution of worker characteristics, determines the wage structure of the economy. The average wage of a person with a particular characteristic relative to the wage of a person with a different characteristic (e.g., the wage of a worker in Paris relative to one in Lyon), all other observed and unobserved characteristics held constant (*ceteris paribus*), is called a wage differential. This article discusses the effects of different worker characteristics on wage structure.

Earnings and Wages

There are several different ways of defining the wage rate, and the appropriateness of any particular definition depends on the questions in which one is interested. Table 1 shows the distribution of average hourly gross (pretax) wage rates of a random sample of workers in the United States in 2011. In principle, one would like to include nonwage compensation (employer contributions for fringe benefits and social insurance programs) but such data usually must be collected from employers rather than from individuals. A worker at the 20th percentile of the distribution earned $9.86 per hour, which means that 20% of workers earned less than this amount. One way to summarize the wage structure is to compare the average wage in the highest quintile (from the 80th percentile up) to the average wage in the lowest quintile (from the 20th percentile down).

These estimated averages for the United States in 2011 were, respectively, $28.80 and $9.86, a ratio of 2.92. An alternative to

Table 1 Estimated distribution of hourly wages of full-time workers in the United States in 2011

Percentile	*Hourly wage*
20	$9.86
40	$13.88
50	$16.07
60	$19.03
80	$28.80

Colombia	13.9
Brazil	23.1
Kenya	18.2
South Africa	32.1
Cote d'Ivoire	7.2

Deininger, K., Squire, L., 1996. A new data set measuring income inequality. The World Bank Economic Review 10 (1), 565–591, Table 1.

the use of hourly wage rates is the use of average weekly, monthly, or annual earnings of individuals. Total earnings per year for an individual are by definition equal to the average wage times hours per year. Data on individual incomes rather than hourly wages are often more readily available in most countries. An example of this is reported in Table 2 in which the ratio of the average annual income of workers in the top quintile to that in the lowest quintile is reported for a selection of countries. The study from which this study was taken includes data for 108 different countries. The dispersion of incomes within a country generally is higher than the dispersion of wages because annual hours tend to be higher for persons with higher wage rates. Notice that for the United States the ratio of the highest to the lowest quintile in terms of income is 8.5, compared to 5.7 for the wage rates of full-time workers. Table 2 shows that there is substantial variation among countries in the dispersion of incomes – as there would be if the data referred to hourly wages rather than annual incomes. A few facts are illustrated by these data. First, there tends to be substantially less dispersion in individual wages and incomes within industrialized countries than in the developing countries. Second, there is much greater dispersion of incomes in the United States than in other industrialized countries. Third, the degree of wage and income dispersion in the formerly socialist countries is relatively low.

The Determinants of Individual Wages

The hourly wage rate (W) of any individual worker in a particular economy at a moment in time will, in principle, depend on a set of observable variables (such as that person's level of completed schooling) as well as on a set of factors that generally are not observed (such as the individual's innate ability, a characteristic that is difficult to measure and usually not obtained in a census-type survey). Let X represent all the variables determining wages that are observed and U represent all the unobserved determinants. We can then specify what economists call an earnings function in which the value of W for each individual depends on X and U according to

$$W = \beta X + \gamma U + \varepsilon \qquad [1]$$

where ε is a random error term (pure 'luck') that is unrelated to the values of X and U.

β is a vector of coefficients representing the effects of each of the observable variables on wages and γ a vector of coefficients representing the effects of the unobserved variables. If, for example, we thought that there were only two observable determinants of W, years of completed schooling (S) and age (A), βX might be specified as $\beta_1 S + \beta_2 A$, and the average effect of an additional year of schooling on W would be β_1.

In practice most estimated earnings functions feature the replacement of the numerical value of W with its natural logarithm. This means that a unit increase in the value of a particular X variable causes W to increase proportionately by the coefficient on that variable. In the case of years of schooling discussed above, with the semilogarithmic form β_1 represents $(\partial W/\partial)/W$ rather than $\Delta W/\Delta S$, if W is entered in numerical form.

From the earnings function given by eqn [1] it is clear that the wage structure, the distribution of W across the working population, depends on both the joint distributions of X and U (as well as the distribution of ε) and the parameters β and γ. Wage differentials, the *ceteris paribus* difference between the average wages of individuals with one characteristic versus another, are determined by the β parameters.

The various determinants of individual wages, both potentially observable and unobserved, can be classified into five groups. These include:

1. skill characteristics
2. job location
3. job characteristics
4. discrimination/nepotism
5. rents.

We will discuss the variables within these groups in turn.

Skill Characteristics

Generally, it is presumed that in most societies, more skilled workers are more productive and that they earn higher wages (*see* Income Distribution and Inequality: Measurement Issues). Two fairly crude but readily observable variables relating to skill of each worker are their years of schooling and potential labor market experience. Some microdata sets allow a more detailed specification of education (what subjects were studied, how many resources were allocated to each year of schooling, etc.) and experience (actual vs potential years, amount of on-the-job-training, etc.) but this sort of detail is rare. An important source of differences in skill and productivity differences among individuals is the variations originating from unobserved ability and motivation. Although a few surveys have included the scores on simple IQ tests, these factors are either largely or completely ignored; that is, they are considered U rather than X variables. This illustrates a general problem associated with the estimation of earnings functions. The true model is given by eqn [1] above, but the researcher is only able to estimate W as a function of observed variables, that is:

$$W = bX + e \qquad [2]$$

where e now represents variation in W that cannot be explained by the observed variables. We know that for most empirical earnings functions e is very important, for the fraction of the variation in W, jointly explained by the observable variables is usually fairly small – between 25 and 35% (see Juhn et al., 1993). There is thus a large potential for empirical estimates of the effects on W of any individual observed variable to be biased upward or downward, due to the correlation of that variable with unobserved variables. In the very simple model above in which schooling and age are the only observed variables, we want to estimate the 'true' effect of S on W from the model $W = \beta_1 S + \beta_2 A + \gamma U + \varepsilon$, but we are forced because of data limitations to estimate $W = b_1 S + b_2 A + e$. The use of b_1 as an estimate of the true effect β_2 is in general subject to specification error, which arises if S is correlated with γU (holding A constant). It seems reasonable to suppose that persons with relatively high levels of intelligence and/or motivation (1) will tend to have higher wage rates (i.e., $\gamma U > 0$) and (2) be more likely to have relatively high schooling levels. This would suggest that b_1 would be an upward-biased estimate of β_1. Interestingly, however, the consensus of the mass of research

into this question (see the review by Card, 1999) is that conventional estimates of the effect of schooling on wages are probably not significantly biased in an upward direction.

Another feature of empirical earnings functions is that their coefficients may change over time. This is especially true for coefficients concerning skill variables. For example, in the US the relative median weekly earnings of full-time workers 25 years of age and above, for those with a bachelor's degree (16 years of schooling) compared to those with just a high school degree (12 years of schooling), rose from 1.56 in 1996 to 1.75 in 2013 (author's calculations from the Current Population Survey). Why these changes in relative wages occurred has received a great deal of attention from economists, but the answer is still a matter of controversy (see Gordon and Dew-Becker, 2008).

Job Location

A second set of observable variables that are usually included in empirical earnings functions are dummy (one/zero) variables describing the location of the worker within the country. Typically the locational variables represent the size of the area in which the person lives (whether or not, for example, it is a metropolitan area with a population in excess of a million) and indicators of residence in particular areas. For example, in a hypothetical study of the determinants of wages in the Great Britain, one would include a large city dummy variable (L_{large}) and separate dummy variables for persons employed in Greater London (L_{london}), other parts of Southern England (L_{south}), and Scotland (L_{scot}). This specification would be represented as $W = b_1 L_{\text{large}} + b_2 L_{\text{london}} + b_3 L_{\text{south}} + b_4 L_{\text{scot}} + \cdots$ with the other observable determinants of wages (the X's in eqn [2]) included. The estimated coefficient b_2 in this earnings function would represent the average *ceteris paribus* wage differential between a person working in London and another working in a large city in Northern England. If, as is generally the preferred approach, W is entered as a natural logarithm, the estimated coefficient b_2 would reflect the approximate proportionate wage differential associated with employment in London.

What is the economic interpretation of coefficients on location of employment? First, because of higher land prices, it is generally more expensive to live in areas with a highly concentrated population. In order for real wages (nominal wages divided by the price level) to be equal across areas, observed wages must be appropriately higher in expensive areas. This would apply especially to very large cities within individual countries – London, Paris, New York, Tokyo, etc. A second reason for the existence of wage differentials by job location is the preferences of workers concerning the characteristics of different areas. For example, living in a large urban area involves greater stress and poorer air quality than living in a rural area, so, holding the cost of living constant, the typical worker might have to be paid a compensating wage differential to work in the large urban area. Similarly, some regions have better weather and other amenities (like public services) than others, and one would expect that wages would be higher in the more desirable than in the less desirable areas in order for potential migrants to be indifferent between different areas. For the United States, the estimated effect on wages of an area having sunshine 80% of the time versus another area having sunshine only 30% of the time, is, as simple economic theory would predict, a reduction of about 7% (Blomquist et al., 1988). This, of course, presumes that all (or most) workers in the economy have the same preferences for the amenities of different areas. To the extent that preferences differ across the population – some people prefer rural areas (warm weather) to large cities (cold), and others the opposite – predictions concerning compensating wage differentials become somewhat less clear. A final reason for the existence of wage differentials across locations is the effect of changes in the structure of labor demand. Suppose, referring to the example above, that there was for some reason a major boom in Scotland that caused the demand for labor there to increase permanently by 50%. It is unlikely that there would be an immediate large migration of workers from England to Scotland, so wages in Scotland would be bid up significantly. The earnings function for Great Britain based on data collected after the demand shift would yield an estimated coefficient b_{scot} that would now be positive. How rapidly the Scottish/English relative wage would return to one (the value of b_{scot} to return to approximately zero) depends on how long it takes for a portion of the British population to relocate to Scotland.

Job Characteristics

In addition to the location of employment, an important set of determinants of wage rates is the attributes of the job held by each individual worker. We can arbitrarily define each job attribute (the set of which we will call A) as 'bad' – the degree to which it is physically onerous, monotonous, a threat to the worker's health and safety, has low social status, etc. It would be expected that higher values of the elements of A would require a compensating differential. Put differently, holding all other (observed and unobserved) determinants of wages constant, the market equilibrium wage of each job would be higher for 'bad' jobs (those with high values of A) than for 'good' jobs (those with low values of A). Thus, for the specification $W = b_1 A_1 + b_2 A_2 + \cdots$, where the A's are numerical representations of bad characteristics (like the injury rate of the job), we would expect to estimate positive b_is.

There are numerous examples of the operation of compensating differentials. (For an excellent introduction to the topic, see Chapter 8 of Ehrenberg and Smith, 2011.) On the other hand, there are many instances in which the estimated effects of certain job attributes tend to be zero or have the 'wrong' sign (from the point of view of the theory) (see Brown, 1980 for a discussion of these problems). An important set of applications of estimates of job amenities on wages is to the question of the economic value of life. If one of the As (say A_1) is the rate of accidental death associated with the occupation of the worker, then one can infer from the estimated value of $\partial W/\partial A_1$, how much individuals value – apart from the opportunity to earn and consume – the continuation of their lives. This information can, in principle, be used to do cost/benefit analyses of programs to reduce risks to life and health.

An example of wage differentials associated with differences in job characteristics is given in **Table 3**. These results illustrate some of the difficulties in the interpretation of the effect of job attributes. The sample refers to individuals working full time in the United States in 1995, who had received a PhD in science or humanities. The regression equation relates the annual salary of each respondent to years since receipt of the doctorate,

gender, race, and region, as well as the field of receipt of the PhD and the current type of employment. The range of field effects (with a PhD in economics equal to 100) is from 73 for humanities to 105 for specialists in computer science. This means that, holding gender, race, years of experience, type of employment, and region constant, the computer humanities relative salary is 1.44. There are also substantial compensation differences across employer types. For example, PhD's employed in the for-profit business sector earn, *ceteris paribus*, 29% more than those in tenure track academic positions.

There are various explanations of why relative compensation differentials of this magnitude exist – in this case among sets of individuals who have the same quantity of education. First, these differentials may reflect compensating differentials in the sense that some fields (economics, for example) are intrinsically boring relative to other fields (like humanities) and require higher monetary rewards in order to induce persons to study them. Some of the relative compensation levels by employer type – for example, the business/academia comparison – most likely reflect premiums that are necessary to get PhDs to work in jobs that are perceived to be less rewarding in a nonfinancial sense.

A second potential explanation of differentials of this sort is that they reflect, in part, average ability differences of the individuals who are in each field or employment type. This is especially relevant for comparisons of employment type in which there is partial sorting on the basis of ability. For example, the compensation difference between academics in tenure track positions and those in both nontenure track positions and lower education (secondary schools and 2-year colleges) is very likely to reflect practices by which the 'better' PhDs are granted tenure.

A third explanation of these compensation differentials is that some of them reflect temporary market factors and there is

Table 3 Estimated relative salaries of PhD's in the United States by field of doctorate and type of employer, March 1995

Figure 1 Adjustment of a labor market to demand shock in the short run and the long run.

a presumption that the high relative compensation of the computer science field in Table 3 is an example of this. This phenomenon is illustrated theoretically in Figure 1. The demand for a particular type of labor is assumed to increase such that the demand curve shifts from D′ to D″. In the short run the supply curve, S_{SR}, is quite inelastic, reflecting the fact that the pool of persons qualified to work in this market is fixed. (In the case of computer scientists, some additional labor can be obtained from people not on the labor force or from closely related fields, but these possibilities are limited.) Thus, the short-run effect of an increase in the demand for this type of labor is an increase in its relative compensation level. In the long run, the supply of labor to this market is very or completely elastic, because new entrants to the labor force can choose to train for this type of work. (In the case of computer specialists, young persons are induced to get PhDs in that field rather than in mathematics or physics.) Over time, therefore, the relative compensation level in this market would be expected to return to its initial equilibrium value, C′, rather than stay at its temporary value, C″ in Figure 1.

Analysis of wage differentials of various sorts can proceed along the above lines. A major example of this is the analysis of average compensation across industries. An example of this is Table 4 in which average weekly earnings across broad industrial groups are reported for the United States. Wages in retail trade, leisure and hospitality, and accommodation and food services tend to be relatively low; wages in mining, information, and finance tend to be relatively high. Some of these differentials reflect quality and compositional differences (that are not adjusted for in the table). But some of the differentials reflect differences in the amenities associated with work in the particular industries.

Gender and Ethnicity

A set of observable variables that are generally included in earnings functions are the demographic characteristics of the workers – his/her gender, race, or ethnicity. For example, the inclusion of a one/zero dummy variable for women as one of the *X*s in eqns [1] and [2] is very common, and the inclusion of motherhood dummy variables is becoming more common (for a summary, see Albelda and Drago, 2013). For the theoretically complete model given by eqn [1], which includes *all* observed and

Table 4 Average hourly earnings of employees by industry, United States

Industry	*Hourly wages*
Mining and logging	$30.80
Construction	$26.57
Manufacturing	$24.71
Wholesale trade	$27.94
Retail trade	$16.84
Transportation	$22.80
Utilities	$35.94
Information	$33.37
Financial activities	$30.53
Real estate	$23.82
Professional and business services	$28.95
Health care	$26.80
Accommodation and food services	$12.89

February 2014 estimates from the Current Employment Survey, US Bureau of Labor Statistics.

unobserved influences on wage rates, the interpretation of the (presumably negative) coefficient on women must be in terms of some sort of labor market discrimination against women. Why else would otherwise identical workers receive lower compensation? The same conclusion applies to conclusions concerning potential dummy variables on race and ethnicity for earnings functions in probably every country in the world (African Americans in the United States, French speakers in Quebec, Arabs in France, natives of Greenland in Copenhagen, etc.).

The problem with attributing the negative effects of gender and certain racial and ethnic distinctions entirely to labor market discrimination is that we are only able to estimate the model for which we have data, eqn [2] rather than the theoretically complete eqn [1] above. Thus, there is the possibility that the negative coefficients on gender and ethnicity reflect, wholly or in part, differences in the average value of omitted variables rather than some form of direct labor market discrimination. Further, it is necessary to know exactly what is the cause of an observed wage differential if a society decides it wants to eliminate this differential (see Altonji and Blank, 1999 for an extensive discussion of these issues).

Recent efforts to overcome these deficiencies involve tests where otherwise similar individuals apply for the same job, while diverging on a single characteristic (such as race, age, gender, or motherhood status). Although these tests are imperfect, they are consistent with the continued existence of labor market discrimination (see Chapter 8 of Albelda and Drago, 2013 for a discussion).

Rents

Most of the above discussion has proceeded as if wages are determined in markets that are similar in process to the markets for melons and equities. The fact that the commodities involved in labor markets are human beings requires that this 'model' be modified to some extent. Indeed, a set of institutions has emerged to provide modification of the outcomes that would follow from the unfettered equilibrium of the labor market. Among these institutions is trade unionism, which has, over time and across societies, taken several forms. Government policy – both directly through legislation determining wages and indirectly through its role as employer – also affects the wage structure. At one level the existence of institutions such as trade unions creates another wage differential of interest. In terms of eqns [1] and [2], being a union member or working in a milieu in which wage rates are determined by a collective bargaining contract means that a worker could earn a higher wage than another worker who is not so situated. In this case, $W = \beta_1 U + \cdots$ is the complete wage equation, including all observed and unobserved variables, where U equals one with union representation and equals zero otherwise. We do not observe everything about the workers and jobs, so we estimate the equivalent of eqn [2], $W = b_1 U + \cdots$.

How good the estimator b_1 is of the 'true' effect of unionism β_1 depends, as in the estimation of other wage differentials, on the correlation of the omitted determinants of wages with U. In the United States, the consensus estimate of the average effect of unionism on wages is about 15% (see Lewis, 1986). A more important effect of unionism and government policy, such as a mandated minimum wage, is their influence on other wage differentials. Although the final word is far from in, research suggests that much of the increase in wage inequality in the United States during the last two decades can be attributed to declining unionization and a declining real minimum wage (for a careful discussion, see Lemieux, 2008). That is, unionization and mandated minimum wages tended to equalize wages for many workers not covered by collective bargaining and/or earning above the minimum wage, and the reach of these institutions has declined.

Abstract

Immanuel Wallerstein's landmark multivolume *Modern World-System* and related works transformed the global intellectual landscape, part and parcel of larger changes in the geopolitics, structures of knowledge, and geoeconomics of the modern world. At once a scholarly analysis and a call to intellectual arms, Wallerstein's formation and personal trajectory demonstrates the importance of both intellectual contexts and social networks for paradigm shifts in the structures of knowledge, away from positive social science and toward a new unit of analysis, that of the study of world-systems, specifically the capitalist world-economy with its single and expanding global division of labor, stratified of course by race, ethnicity, class, gender, and nationality. This article provides an overview of Wallerstein's formation and career as a scholar-activist, including family origins, education, networks, historical context, and main achievements. The article includes a brief description of some of Wallerstein's major works and discusses their legacy and lasting impact, including in terms of his call for a unidiscplinary historical social science and possibly even beyond, that with moves toward overcoming what C.P. Snow called The Two Cultures dividing the social sciences, humanities, and the natural sciences, a unique feature of the structures of knowledge of the modern world-system.

Biographical Introduction

Immanuel Maurice Wallerstein, currently a senior research scholar at Yale University, was born on 28 September 1930 in New York City. Wallerstein, today a member of the American Academy of Arts and Sciences, is widely considered to be among the most accomplished critical social scientists of his era, since the publication of his landmark work, *The Modern World-System: Capitalist Agriculture & the Origins of the European World-Economy in the Sixteenth Century* (1974). Wallerstein did both his undergraduate and graduate work at Columbia University – (BA, 1951, MA, 1954, PhD, 1959) and went onto become a tenured professor in its Department of Sociology. As a graduate student, Wallerstein's scholarly and related political interests led him to do extensive field work, travels, and interviews in the Third World, uniquely among the major US social scientists of this period, notably in Francophone West Africa (but traveling throughout the continent), this during the period of colonialism and mobilization was against colonial rule. Wallerstein also spent time in Western Europe, notably Paris, where he met many of the critical diaspora intellectuals from Africa, Latin America, Asia, and the Middle East and his time in France also introduced him to the work and person of Fernand Braudel, one of the chief analysts of capitalism over the *longue duree*, as well as arguably the greatest historian of the twentieth century and the second generation leader of the Annales school, after Lucien Febvre and Marc Bloch, with its emphasis on geography and history. Along with Marxism, the German historical school and Latin American dependency theory, these emphases played critical roles in Wallerstein's career as one the world's foremost scholar-activists and public intellectuals and what Randall Collins called the golden age of (comparative) historical sociology of which Wallerstein has played such an integral part.

Wallerstein came of age during the heyday of post–World War II modernization or development theory as explicated most elaborately by Harvard Sociology's Talcott Parsons, the dominant consensus theorist of the American Century, akin to England's Herbert Spencer during the era of British hegemony, as well as by Walt Rostow (1960) in his *The Stages of Economic Growth: A Non-Communist Manifesto*. In this Whig interpretation of history, states, synonymous with society, are the primary units of analysis and seen as developing along parallel lines from traditional agricultural societies to modern urban-industrial societies based on high mass consumption. At once a cultural explanation of world inequality, modernization theory was simultaneously a political program for 'progress' and a central tenet of US foreign policy in the age of decolonization and national liberation movements. As the US and the Soviet Union squared off in the Cold War superpower confrontation, both the US and USSR touted themselves as embodying modernity – capitalism and communism respectively – telling the newly liberated Third World and those undergoing decolonization that it was best to join sides of one of the superpowers so as to develop and become modern. For Wallerstein, however, a much more basic conflict than this one, of which it was arguably a part, was the more fundamental North–South conflict and it was toward an understanding of and overcoming this divide that he would devote his scholarly career.

As Walter Goldfrank (2000: 153) notes in the most cogent sociological assessment of this Wallerstein's work to date,

> It is difficult to imagine Wallerstein's having come to consciousness outside of New York City … New York was where the action was in business and finance (Wall Street), in fashion and advertising (Fifth and Madison Avenues), in publishing and high culture. Like the London of Marx's maturity, the New York of Wallerstein's youth … was … the prime vantage point for seeing the world as a whole. Wallerstein's work is very much that of the inveterate New Yorker looking for the big picture, the politically savvy New Yorker looking through the ethnic garb of class struggles, the Jewish New Yorker deflating the pretentious claims to legitimacy of an Anglophile New England elite.

And it was at Columbia, too, as Goldfrank also pointed out, under the mentorship of C. Wright Mills, who he later contributed an entry for the *International Encyclopedia of the Social Sciences* (1968), that Wallerstein was likely influenced by Mills "two-front sociological attack on Grand Theory and Abstracted Empiricsm," then deployed against Talcott Parsons, which Wallerstein in turn used against the split in the social sciences between nomothetic universalizing theoretical disciplines (sociology, economics) and idiographic descriptive particularistic empirical ones (history, anthropology). From Mills too, helped along by Braudel, *Annales* and the German historical school, there is the historicism, attention to macro-structures and disdain for positivist US social science, which has characterized all of Wallerstein's work. Also important, from Wallerstein's travels in Africa and Paris, was his introduction to the literature on *negritude* associated with Aime Cesaire, Leopold Senghor (later President of Senegal), Leon Damas, and others. And perhaps even more importantly for Wallerstein, it was in Accra that he met Frantz Fanon, theorist and activist of the Algerian revolution, soon to become famous for his *The Wretched of the Earth*, which Wallerstein helped to get translated into and published in English.

Intellectually, though, along with the Third World radicalism that Fanon personified and which would be central to world-systems analysis, arguably most important were Marx and Engel's, especially their laser-like focus on the division of labor and social conflict between materially based human groups, all of which is at the heart of Wallerstein's world-systems perspective, but with a global eye, rather than the myopic blinders of the nation-state, which still occluded Marx's otherwise world encompassing historical vision of capital. Moreover, Wallerstein was at Columbia University during the world revolution of the 1968, as students occupied parts of the university to protest the Vietnam War and related issues. This was a real wake up call. Wallerstein was one of the few faculty trusted by the students and served as a member of the Executive Committee of the Ad Hoc Committee of Concerned Faculty. The experience pushed Wallerstein to the left politically, led to his departure from Columbia and eventually to his writing and publication of *The Modern World-System*.

As Thomas Kuhn (2012) and Randall Collins (1998) have argued in different but complementary ways, paradigm shifts in the structures of knowledge occur over long-periods. And just as paradigms are not built in a day, neither do they often fall overnight. Though in a variety of ways, key aspects of the main tenets of Wallerstein's world-systems analysis had been adumbrated before, notably by Africa diaspora intellectuals such as W.E.B. Du Bois and Oliver Cox, it was Wallerstein that first put them all together, albeit in a startling original synthesis, with many new features never before articulated. Here, too, the timing was just right. After the promissory note of developmentalism and domestic equivalents such as the War on Poverty gave way to the realities of the Vietnam War some 50 years ago, with social science luminaries such as Walt Rostow, who went onto become President Johnson's National Security Adviser, leading the way, the objectivity of the modernization paradigm was increasingly questioned. The cracks in the liberal consensus and turmoil at universities were part and parcel of a much broader wave of social movements and social conflict in the US and around the world, including over the appropriate paradigm to study social change. Here, following the success of Latin American dependency theory, centered around the Economic Commission on Latin America, and articulations of the development and underdevelopment by Latin American dependency theorists such as Andre Gunder Frank, Wallerstein's *Modern World-System* was a bold frontal attack, akin to Galileo's *Dialogo on the World Systems* and related works, or linguist Noam Chomksy's frontal assault on B.F. Skinner and behaviorism beginning in the 1950s and 1960s.

Most critical and enduring here was Wallerstein's critique of social science's modernization paradigm's unit of analysis, the state, seen as synonymous with society, developing along parallel lines. In sharp contrast, animated by socialist ideals of liberty, fraternity, equality, albeit in sharp contrast with actually existing socialism and global capitalism, Wallerstein reconceptualized social change as taking place within social systems, defined, as in Marx and Engel's *German Ideology*, where they laid out their vision of historical materialism, by the division of labor. But while Marx and Engels still remained trapped in the conceptual tyranny of the nation-state, for Wallerstein's capitalism was always a global system, with a single or increasingly global division of labor – radically stratified by race, ethnicity, class, gender, nation, and geographic location – and indeed as he set out to show, could not have been otherwise.

In what Wallerstein called "the long sixteenth century," following the formation of the regional forerunner of the capitalist world-economy in the Italian city-states, a new modern world-system was born, a European centered capitalist world-economy, based especially on the bringing together of (Latin) American resources, African (slave) labor power, and Asian markets. Here then was the proper unit – totality really – to study social change. Equally as important, Wallerstein argued that there developed a tripartite zonal distribution of the capitalist world-economy and interstate system, within which a polarization of wealth and power took place between rich core states and poor peripheral states, with a middling sector, the semiperiphery, playing an intermediate role. And, as can never be overemphasized, the designations of core, periphery, and semiperiphery are relational categories representing ongoing relational processes of the polarization of wealth and power in the capitalist world-system.

The Modern World-System

As many have noted, Wallerstein will likely be judged by his major work, *The Modern World-System*, now at four volumes, the first three of which have just been republished with new forewords by the University of California (UC) Press. Significantly, Wallerstein's "Introduction" to Volume I of this work is subtitled "On the Study of Social Change," and it is here that the method and research program, which he has followed all of his life was first laid out. The focus here is on the major watersheds in human history, specifically modernity, or the birth of the modern world. Unlike a generation of social scientists with their studied neutrality and objectivity, Wallerstein situated himself as an actor – a scholar to be sure,

but a committed one – in the global system. Wallerstein then relates how the African prism, as one scholar called it, led him to search for and then question what was the appropriate unit for studying social change and to be properly skeptical about "the degree to which society as an abstraction was heavily limited to politico-juridical systems as an empirical reality." So it was that Wallerstein came up with his alternative conceptualization of social systems, as defined by a single division of labor, transgressing the nominally sovereign boundaries of territorially based states and thereby reflecting economic interdependence, as the appropriate totality/unit of analysis for studying social change. The unique aspect of the modern world-system, Wallerstein then argued, was that it was based on the creation of a new type of social system that had never before existed, the capitalist world-economy based on a single division of labor and replete with an interstate system, which became simultaneously the first social system to encompass the entire globe.

After an initial chapter entitled "Medieval Prelude," Wallerstein articulated "The New European Division of Labor: *c*. 1450–1640," thereupon moving to the question of absolutism and then Spain's bid for world-empire, contrasted conceptually with the concept of the capitalist world-economy. Here we see a critical part of Wallerstein's method: analytical concepts and the process they designate are contrasted conceptually and empirically with each other, so that the core states of Western Europe are contrasted with Eastern Europe, the island states of the Caribbean and last but not least the remnants of the Spain's Hapsburg Empire, which largely become part of the semiperipheral zone. As with Marx, wealth and poverty here are conceptually and empirically entwined, albeit here in relational concepts of core, semiperiphery, periphery, and related geoeconomic regions, and in a global rather than a national context.

Here, development and underdevelopment result not from temporal lags in progressing toward modernity but are instead seen as an expression of the oligarchic wealth on which the capitalist world-economy is necessarily based, as Wallerstein's friend and colleague Giovanni Arrighi, author of (2010) *The Long Twentieth Century: Money, Power & the Origins of Our Times*, and (2009) *Adam Smith in Beijing: Lineages of the 21st Century*, has shown. In addition, the tripartite zonal division of the capitalist world-system is seen as concomitant with variegated modes of labor control in these zones, with nominally free wage labor more prevalent in the core and varieties of coerced labor more common in the periphery and semiperiphery. In the remainder of the book, Wallerstein looks at the formation of the core state of the capitalist world-economy, before going onto chronicle the formation of peripheral zones and to contrast these with those areas external to the operations of the world-economy, after which there is a "Theoretical Reprise" reflecting on the book as a whole.

Only in Volume II (1980), subtitled *Mercantilism and the Consolidation of the European World-Economy*, does Wallerstein fully do justice to "Dutch Hegemony in the World-Economy," as one of the early chapters is called, focusing thereafter on interstate competition among the core powers, before turning to peripheries, semiperipheries, and then back to the core. Here was more fully adumbrated the theory and empirical realities of the rise and fall of hegemonic powers in the world-system, in an analysis developed more fully, albeit in radically different ways, by leading world-systems scholar and historian of capitalism, Giovanni Arrighi. Wallerstein's Volume III (1989), *The Second Era of Great Expansion of the Capitalist World-Economy, 1730s–1840s*, offers too, like Volume I, a radical reinterpretation of modern world history. In the first chapter, "Industry and Bourgeoisie," Wallerstein dispenses simultaneously with the notion of both bourgeois revolutions, using the French Revolution as the paradigmatic example, as well as with the Industrial Revolution (the former conceived as anticapitalist despite its almost universal designation as a bourgeois revolution). Here the notion of the British industrial revolution is seen as an expression of British conceit and related ideologies of modernization, concealing the processes of industrialization as a global process centered on England rather than a national British event.

Wallerstein then chronicles the ascendancy of British hegemony in the context of the Napoleonic wars, before going onto deal with the incorporation of Russian and Ottoman empires, as well as India and West Africa, into the capitalist world-economy. The final chapter, "The Settler Decolonization of the Americas," includes analyses of the American and Haitian revolutions and the independence struggles that led to the decolonization of Latin America. Volume IV, subtitled *Centrist Liberalism Triumphant, 1789–1914*, involves in many ways a radical departure from Wallerstein's previous three volumes in its focus on the politics of the world-system rather than on the economics. In the foreword, Wallerstein lays out a prospectus for the rest of his project, namely a Volume V from 1873 to 1968/89 and a possible Volume VI which promises to chronicle the history of the modern world-system right up to the present and to project ahead to somewhere in the mid-twenty-first century, perhaps to 2050.

Over these many decades, too, Wallerstein has published widely, with numerous books, articles, and collections of essays, from his three volume *The African Liberation Reader: Documents of the National Liberation Movements* (with Aquino de Braganca) (1982), the landmark *Antisystemic Movements* (with Giovanni Arrighi and Terence Hopkins) (1989), to *Geopolitics and Geoculture* (1991), *Creating and Transforming Households* (with Joan Smith and others) (1992), *European Universalism: The Rhetoric of Power* (2006), and *Race, Nation, Class* (with Etienne Balibar) (2011). But it is likely that when all is said and done, Wallerstein will be remembered most, after his work on the capitalist world-economy and related inequalities of race, ethnicity, class, and gender, for his work on the structures of knowledge of the modern world-system, part of a larger critique of Eurocentrism and the coloniality of power associated most especially with the work of Edward Said and Peruvian Sociologist Anibal Quijano, respectively. Most important here, along with his *Unthinking Social Science* (2001), the three volume collection of discussions with leading thinkers, *Questioning Nineteenth Century Assumptions About Knowledge* (with Richard Lee) (2010), is *Open the Social Sciences: Report of the Gulbelkian Commission on the Restructuring of the Social Sciences* (1992). Yet it is important to note that all of this work is the outcome of a lifetime spent rejecting and critiquing the premises of mainstream social science and formulating an alternative more holistic vision, drawing on a host of leading albeit iconoclastic scholars such as the institutional economist Karl

Polanyi. Already, at the end of the Introduction to Volume I, Wallerstein (1974: 11) noted:

> When one studies a social system, the classical lines of division within social science are meaningless. Anthropology, economics, political science, sociology – and history – are divisions of the discipline anchored in a certain liberal conception of the state and its relation to functional and geographical sectors of the social order. They make a certain limited sense if the focus of one's study is organizations. They make none at all if the focus is the social system. I am not calling for a multidisciplinary approach to the study of social systems, but for a unidisciplinary approach. The substantive content of the book will, I hope, make it clear what I mean by this phrase and how seriously I take it.

In *Open the Social Sciences*, Wallerstein and his coauthors trace the specificities of modernity's structures of knowledge, most especially what C.P. Snow (2013) referred to as *The Two Cultures* – the unique division between the arts, humanities, and social sciences. Wallerstein chronicles, too, the formation of the modern-day university system in England, France, Germany, Italy, and the US, noting the overwhelming preoccupation of those countries in studying about themselves and the Euro-American world. For as conceptualized by Eric Wolf, there was only *Europe & the People Without History* (2010). Over time, of course, with the emergence of area studies, borders between the disciplines began to break down, leading to widespread calls for the reorganization of the structures of knowledge to which Wallerstein has added his own voice. In subsequent works Wallerstein takes heart from the introduction of historicity, notably the arrow of time, into the natural sciences. Here, Wallerstein finds inspiration from a member of his Gulbelkian Commission, winner of the Nobel Prize in Chemistry for his work on nonlinear (thermo)dynamics, Ilya Prigogine, and the mathematician, Ivar Ekeland.

Simply put, it is hard to think of another work, project really, in the historical social sciences that had a greater impact across disciplinary boundaries than *The Modern World-System*. The work is routinely cited in almost all critical accounts of development or modernization theory and often times by scholars working on particular geographic areas. It permanently altered the intellectual universe of world social science and intellectual culture more generally; not because modernization theory has become a minority position, quite the contrary, especially with recent analyses of *The Ends of History* but instead because alternative critiques can no longer be ignored, and equally as importantly because there are now an increasing body of scholars, inspired in no small part by the work of Wallerstein and his cohorts, presenting cogent scholarly accounts of world history and global inequalities, from the Paleolithic to the present, from a world-systems perspective. Indeed, in many ways, for all its problems, contemporary accounts of globalization – not to mention the current ecological crisis in the age of the Anthropocene – reflect a growing awareness of global interdependence first presented in Wallerstein's work. Before the publication of *The Modern World-System*, European economic history and that of the Third World were almost always presented separately; not so any more, at least as a matter of course.

Here, it is important to note that the intellectual contributions of Wallerstein have been combined with concentrated activity in providing a base for world-systems analysis as an intellectual social movement. With the assistance of his long-time friend and colleague Terence K. Hopkins from Columbia, Wallerstein established a unique graduate program at the State University of New York (SUNY) Binghamton, as well as the Fernand Braudel Center for the Study of Economies, Historical Systems, and Civilizations, with its annual journal *Review*, and related Research Working Groups, making it for some time the key locus for world-systems studies. Simultaneously Wallerstein formed the Political Economy of the World-System section of the American Sociological Association, virtually unique too in its annual conferences and concomitant publication of a yearly volume, with the *Journal of World-Systems Research*, now its official peer-reviewed journal (and the first free open-source one to be established).

Intellectual Influence and Legacy: Lasting Impact and Possible Futures

In the beginning of *The Modern World-System*, Wallerstein noted that it is widely recognized that there have been a series of epochal changes in human history, in the context of discussing the proper spatiotemporal framework for the study of (inequality in) the modern world-system and the need to look at historical capitalism over the *longue duree*.

> One such generally recognized watershed, though one however studied only by a minority of social scientists, is the so-called Neolithic or agricultural revolution. The other great watershed is the creation of the modern world.

> This latter event is at the center of most contemporary social science theory, and indeed, of the nineteenth century as well ….

> … there is no area of study that is not "relevant." For the proper understanding of the social dynamics of the present requires a theoretical comprehension that can only be based on the study of the widest possible range of phenomena, including through all of historical time and space.

To be sure, Wallerstein has not personally heeded his own call to go back into the premodern past to understand the present, though many of his colleagues – one thinks especially of Christopher Chase-Dunn, Director of the Institute for Research on World-Systems at UC Riverside – have. But it would perhaps not be too much to say that by helping to reorient the social sciences and the humanities toward the study of global inequality – something now increasingly being investigated in the natural sciences as well, what with climate change – Wallerstein helped to create the wave of studies that have done exactly this, most especially by analyzing that other major watershed of human history, the Neolithic revolution, indispensable for our understanding of modern inequalities. One thinks here most especially the work of Alfred Crosby, *The Columbian Exchange* (2003), *Ecological Imperialism: The Biological Expansion of Europe, 900–1900* (2004), and Jared Diamond's

Pulitzer Prize winning *Guns, Germs & Steel: The Fates of Human Societies* (2004).

By widening the spatiotemporal horizons of scholars interested in modernity, global inequalities and by helping bring back space and time, as well as geography, history, ecology, climate, and epidemiology into the social sciences, following the tradition of the *Annales* and German historical schools, not to mention by updating Marx's social conflict analysis for a new millennium and in a global vein, Wallerstein has fundamentally reshaped the terrain of global intellectual culture and scholarly inquiry. Moreover, as the virtual inventor of an intellectual social movement, something fairly rare in the structures of knowledge of the modern world, and as an indefatigable scholar and organizer in its knowledge structures (most recently in his capacity as President of the International Sociological Association from 1994 to 1998), Wallerstein has also become a public intellectual cited by both scholars in the ivory tower and scholar-activists in social movements outside its hallowed halls, including in the World Social Forum(WSF). The rise of world-systems analysis is of course part of a broader critique of developmentalism expressed in movements such as the Zapatistas, the WSF, and among Latin American social movements, with their concept of *buen vivir*: a state of living well (Esteva et al., 2013). Proponents of and sympathizers with world-systems analysis can now be found among leading scholars and activists across the globe, whose manifold contributions to the study of the world-system have been amply discussed elsewhere. By opening up the question of the proper unit of analysis for the study of social change and forwarding his own, the single division of labor, Wallerstein has contributed to a veritable revolution in the structures of knowledge, opening up vast new spaces inside and outside of the academy. Turn to any academic discipline in the social sciences or humanities today and you will find Wallerstein's world-systems analysis cited, debated, and discussed.

There are, to be sure, lacuna and unanswered questions. Though it has seldom been commented on, as noted above there was always a conscious analogy, if understated, in Wallerstein's work, to Galileo's *Dialogo*, and to astronomy and physics more generally, as intimated in the introduction to the *Modern World-System*.

> There had only been one "modern world." Maybe one day there would be discovered to be comparable phenomena on other planets, or additional modern world-systems on this one. But here and now, the reality was clear-only one. It was here that I was inspired by the analogy with astronomy which purports to explain the laws governing the universe, although (as far as we know) only one universe has ever existed.

> What do astronomers do? As I understand it, the logic of their arguments involves two separate operations. They use the law of physics, and argue that … these laws hold by analogy for the system as a whole. Second, they argue a posteriori. If the whole system is to have a given state at time y, it most probably had a certain state at time x.

At the time of Wallerstein's writing, not only were the social sciences far from the unidiscplinary historical social science he called for (virtually alone), as they still are today, but also there were even greater barriers separating the natural and the social sciences, as well as the humanities, from each other. Since that time, there has been a noticeable blurring of the lines not only in the social sciences but between these and the natural sciences and humanities as well. Indeed, as many scholars are now becoming increasingly aware of, all forms of life on the planet earth are related to each other and moreover, everything in the universe is related, as Neil Shubin (2009, 2013) has shown in *Your Inner Fish: A Journey into the 3.5 Billion Year History of the Human Body* and more recently in *The Universe Within: The Deep History of the Human Body*. As to the question of how many universes, even this is question in the age of speculation about multi-universes. We can thus see today that Wallerstein was well ahead of his time with his call for a unidiscplinary social science, his drawing attention to the unique modern split between *The Two Cultures* as identified by C.P. Snow and his related trespasses and explorations into the natural sciences as well, borrowing concepts from the latter to analyze the former. Most significant here is Wallerstein's argument, taking from Prigogine's work on chaos theory and nonlinear dynamics of systems moving far from equilibrium and related moments of bifurcation, that we are living in a period of the terminal crisis of the capitalist world-economy and birth of new alternative system(s).

A curious omission here is the nature of humanity itself, as different from other animal species and that of course raises the question of language – only some 50 000 years old – and Chomsky's theory of universal grammar, neglected, with some rare albeit important exceptions by world-system scholars and most social scientists as a whole. And yet, as Wallerstein's own colleague and collaborator Ilya Prigoine (with Isabelle Stengers) noted, "… we need an account of the material world in which it isn't absurd to claim that it produced us" (quoted in Terrence W. Deacon's (2012: 143) *Incomplete Nature: How Mind Emerged from Matter*) and the us, humanity, must certainly include an analysis of how so-called mind, human consciousness, or language, emerged from matter, to use layperson's terms. Such questions, to varying extents, into the nature of language and humans were at the heart of the entwined cognitive and scientific revolutions of the seventeenth century, as recognized by Galileo, Descartes, Locke, Hume, and others, as Emeritus Professor in Linguistics and Philosophy at MIT, Noam Chomsky has argued for many decades, notably in his *Cartesian Linguistics: A Chapter in the History of Rationalist Thought* (2009).

The question of the nature of human and human language have been examined in great detail by Noam Chomsky, including recently in his chapter "The Mysteries of Nature: How Deeply Hidden," in Jean Bricmont and Julie Franckm eds, *Chomsky Notebook* (2009) and "The Faculty of Language: What Is It, Who Has It, and How Did It Evolve?," (with Marc D. Hauser and W. Tecumseh Fitch) in Richard K. Larson, Viviane Deprez, and Hiroko Yamakido, eds, *The Evolution of Human Languages: Biolinguistic Perspectives* (2010), the latter calling for interdisciplinary work so as to examine the biolinguistic capacity of humans. Chomsky himself argues that the entire field of cognitive science remains largely at the pre-Galilean stage because of unfounded assumptions and hence has drawn attention to the scientific breakthroughs of Isaac

Newton, with his concepts of action at a distance and gravity, exorcising the machine but not the ghost, at once lowering the expectations for science, thereby paving the way for progress in the field, or normal science. What is especially ironic, here, as has been pointed out by Chomsky and others, is that Newton destroyed the mechanical philosophy and related ideologies of materialism just at the time when these doctrines became ever more influential and to be sure, the legacy of (historical) materialism can be seen in world-systems analysis right up to the present, remnants of the old battle against (Hegelian) idealism.

It remains to be seen of course, whether and to what extent Wallerstein's call for an unidisciplinary social science will be taken up and whether this might be joined with developments in the natural sciences, most especially in terms of our understanding of human language and hence humanity itself as part of natural and social evolution; or whether, and to what extent, the growing realization of the connection of all knowledge and life in the universe, will lead to new revolutions in the structure of knowledge and new understandings of what kind of species we humans are, as one of Noam Chomsky's lectures at Columbia University in the Fall of 2013 was recently titled. That these questions can even be formulated, however fleetingly though, is testament to a life well lived, albeit of course still being lived, of a trail blazer in, and reshaper of the structures of knowledge, who has made and is continuing to make, along with that of his colleagues, enduring contributions to an understanding of the present world-system, so as to encourage greater respect for nature and other human beings and living species, and to changing it as well.

Abstract

This article examines the life and work of Michael Walzer (1935–present), whose many roles include professor, moral philosopher, critic, editor, activist, public intellectual, social democrat, American Jew, and devoted family man. He is the author or editor of 35 books from 1965 to 2012, 11 in other languages, and 437 articles, essays, and book reviews from 1956 to 2012. Walzer's work is characterized by a concern for equality and diversity within, and between, communities, bound by a shared culture that provides the basis for moral critique, political action, and democratic participation in decision-making and progressive social change.

Michael Walzer was born in New York City in 1935 to first-generation Jewish immigrants from Austria, Galicia, and Belarus, and was raised in the Bronx. His father worked in the fur trade, but went bankrupt during the economic downturn of 1937–38, and subsequently worked in a factory involved in war production until 1944. At 9 years of age, his family moved to Johnstown, Pennsylvania, a steel town east of Pittsburgh, where his father had been offered a job managing a jewelry store (Williams, 2012: 3). His parents were political supporters of the anti-Stalinist left, reading the popular front daily newspaper, PM, and later I.F. Stone's Weekly. At the time, Johnstown was both a strong trade union town dominated by work in Bethlehem Steel, and a New Deal, liberal Democratic Party stronghold. Walzer describes his upbringing as growing up in a 'lefty household' with politics as 'the daily conversation' of everyday life (Michael Walzer: Who Are You?).

At 17, Walzer attended Brandeis University in Waltham, Massachusetts, a nonsectarian, Jewish community sponsored, coeducational institution that had been established in 1948, where he met other 'Jewish red diaper babies and Jewish lefties of different sorts' (Michael Walzer: Who Are You?). During his undergraduate years at Brandeis from 1952 to 1956, Walzer took courses with Irving Howe and Lewis Coser, members of the New York Intellectuals group (Williams, 2012: 3). In 1954, he was invited to the first issue launch party of *Dissent*, a social democratic magazine founded by Howe and other ex-Trotskyists. *Dissent* attempted to define a democratic socialist, third position between Soviet communism and American liberalism (Reiner, 2011: 199). It sought to identify and retain socialist beliefs and practices that remained relevant and useful, particularly in the American context, while incorporating features from liberal democracy such as individual choice, a market economy, and democratic decision-making (Reiner, 2011: 199, 200). This shows an ideological pluralism in Walzer's thought that remains characteristic of his work throughout his life, and is one of the reasons that singular labels such as socialist, liberal, conservative, or communitarian are difficult to apply to his work.

Walzer was asked by Howe to write his first article for *Dissent* in 1956 concerning the CPUSA's (Communist Party USA) response to Krushchev's speech about Stalinism. Working and writing for *Dissent* became a significant part of Walzer's life until his retirement from the magazine in April 2013 (*Dissent's* Sixtieth, 2013). Howe sent Walzer to the American South in 1960 to write about the sit-ins, and he became an active participant in the civil rights movement until Jews and other Whites were invited to leave by Black Nationalists in 1967. He then focused his political activism in the anti-Vietnam War movement and, more broadly, in the American social democratic left (Williams, 2012: 4, 5). While still actively contributing articles, he became an editor at *Dissent* in 1976 (and a contributing editor to *The New Republic* from 1977) and, after Irving Howe's death, coeditor of *Dissent* for 20 years from 1993 (Tracy, 2013: 1).

The influences of democratic socialism, Irving Coser, *Dissent* magazine, and his political activism are most directly expressed in *Political Action* (1971) and *Radical Principles* (1980). *Political Action* is a description and critique of citizen activism in the United States from an insider's perspective following the American invasion of Cambodia during the Vietnam War (1971: 9). Political action involves 'action with or for others' for public reasons to have effects on 'other people as well as ourselves' (1971: 18). Its purposes are to expose injustice and oppression and oppose it through mobilization, revolt, and social change (1971: 120, 121). In the American case, political action addresses the sense of powerlessness experienced by many Americans who believe that 'effective control' of government and the economy has been gradually taken away from citizens (1971: 121). Walzer offers practical advice for political organizations, noting in particular that the specific cause that unites activists reflects only a part of their lives; the other parts of their lives may overlap with each other, opening political space for coalitions or alliances with other groups based on different causes (1971: 32, 40, 41). This shows a concern for organizational pluralism that complements his ideological pluralism. *Radical Principles* (1980) is more focused on the prospects for democratic socialism in the United States. The book is a collection of articles published between 1964 and 1979 in *Dissent* and *The New Republic*. It is dedicated to Irving Howe, Lewis Coser, and 'all my comrades on *Dissent*' (1980: v). The common theme revolves around the question of how the principles of democratic socialism can be maintained and renewed in response to significant changes in the United States during the 1960s and 1970s (Reiner, 2011: 51).

While at Brandeis, Walzer met Judith Borodovko, another student of Howe's, and they married in 1956, after Walzer

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61304-1

graduated summa cum laude with a BA in History from Brandeis. They had two daughters born in 1961 and 1964, and later grandchildren. Along with his work at *Dissent* and his political activism, family and the Jewish community have been central to Walzer's life. His wife in particular became one of the main interlocutors of his work; he calls her, after 60 years together as a couple, "my closest comrade and smartest critic" (*Dissent*'s Sixtieth 2013). Extending beyond yet interrelated with his family, Walzer's "deepest personal connection is with the American Jewish community" (Morton, 2013: 6). This reflects his background as an American Jew who grew up in the aftermath of World War II, the Holocaust, the founding of the state of Israel, and the increasing acceptance of American Jews as an ethnic and religious group in American society. In the preface to *On Toleration* (1997), Walzer notes that "as an American Jew, I grew up thinking of myself as an object of toleration" (1997: xi), and that this background helps to explain his support for religious, ethnic, and national pluralism in the United States and across the world. Walzer also describes himself as having been "a Zionist ever since my bar mitzvah" in 1948 in Johnstown and as a half-immigrant to Israel (*The State of Righteousness* 2012). He has been a member of the Board of Governors of the Hebrew University of Jerusalem since 1974, and is a member of the editorial board of the Jewish Review of Books.

Jewish themes are prevalent in many of Walzer's major works. These include a dedication to those killed in the Holocaust drawn from an inscription at the Yad Vashem memorial in Jerusalem, and an examination of the 1967 Six Day War in *Just and Unjust Wars* (1977); discussions of A Medieval Jewish Community, The Israeli Kibbutz, and The Idea of the Sabbath in *Spheres of Justice* (1983); and a chapter on the biblical prophet Amos in *Interpretation and Social Criticism* (1987). His first book on solely Jewish themes was *Exodus and Revolution* (1985). Fifteen years later, he coedited two volumes on the Jewish Political Tradition on authority (2000) and membership (2003). These were followed by an edited book, *Law, Politics, and Morality* (2006), and Walzer's most recent sole-authored book in English, *In God's Shadow: Politics in the Hebrew Bible* (2012).

After Brandeis, Walzer studied at the University of Cambridge in the 1956–57 academic year on a Fulbright Fellowship. Under the supervision of Geoffrey Elton, he began to research English history in the sixteenth and seventeenth centuries (Reiner, 2011: 4). At the end of the fellowship, Walzer began his doctoral studies in the Department of Government at Harvard University, earning his PhD in Government in 1961. His adviser, Samuel Beer, was a major influence on Walzer with respect to his dissertation topic on the development of Calvinism as a political movement in seventeenth-century England. Beer influenced Walzer's use of historical idealism as a conceptual framework in which "ideas are dependent on particular historical and social contexts and cannot be understood in abstract from those contexts," and as a method of "using history illuminate theory and testing theory with historical cases" (Reiner, 2011: 15, 18). Carl J. Friedrich, Louis Hartz, and Barrington Moore also had an impact on Walzer at Harvard in terms of historical idealism, and comparative historical analysis in Moore's case (Reiner, 2011: 18). These influences are evident in the publication of Walzer's doctoral dissertation as his first book, the *Revolution of the Saints* (1965), and *Regicide and Revolution* (1974), which was dedicated to Beer.

Walzer was hired as an Assistant Professor at Princeton University from 1962 to 1966, before returning to Harvard as a Professor from 1966 to 1980. *Obligations* (1970) was based on lectures that Walzer gave at Harvard between 1966 and 1969 (1970: v). While at Princeton, Walzer became involved with a community of philosophers including Robert Nozick and Thomas Nagel (Reiner, 2011: 5). Nozick and Nagel organized a discussion group, the Society for Ethical and Legal Philosophy (SELF) in 1967, and the journal *Philosophy and Public Affairs*, founded with group members in 1971 (Nagel, 2013: xi). Walzer was an integral member of the group that included, among others, Ronald Dworkin, John Rawls, and Judith Jarvis Thomson, presenting work at their monthly meetings. Nagel describes the group as 'united by two convictions' (Nagel, 2013: xii). The first was 'a belief in the reality of the moral domain' in which 'there are real questions with right and wrong answers'; the second was 'a belief that progress could be made toward discovering the right answers' (Nagel, 2013). Group members applied 'analytic methods of reasoning and argument,' including 'imaginary cases,' to 'examples of conduct and policy' to reveal the 'principles determining right and wrong, justice and injustice' (Nagel, 2013: xii, xiii). In a 2003 interview, Walzer acknowledged the influence of SELF on his work, particularly Nozick and Rawls, stating that he "spent much of the 1960s and 1970s learning to 'do' philosophy" and that, as a result, he made "an effort to write about politics in a more philosophical way" (2007: 307, 308). However, he adds that "I quickly got impatient with the playful extension of hypothetical cases, moving farther…away from the world we lived in" (2007: 308).

Walzer spent much of the 1970s writing *Just and Unjust Wars* (1977), his response to 'the American intervention in Vietnam' and his political activism in the antiwar movement (1997: xix). The book acknowledges the importance of SELF and individual members, particularly Nozick and Thomson (xxvii). It provides an analytical treatment of practical morality in our shared moral world, looking 'to recapture the just war for political and moral theory' (1977: xxii) by secularizing 'Catholic just-war doctrine' (Williams, 2012: 5). Walzer adds that his "decision to work the argument through historical examples was in part a reaction against the hypothetical cases of my friends" in SELF (2007: 308). The book is also an application of the historical idealism and comparative historical analysis that he learned at Harvard. In particular, the book analyzes the case for, and cases of, the justice of war or *jus ad bellum* from justice in war or *jus in bello* (1977: xxiv), emphasizing the human rights of life and liberty as 'something like absolute values' that should provide a moral limit to utilitarian and realist arguments about going to and conducting war (1977: 21).

Walzer supports the doctrine of nonintervention based on the presumption that just wars are defensive wars, and on the right of individuals to exercise collective self-determination as a national community in their sovereign territory (Reiner, 2011: 74, 178). This shows Walzer's belief in international pluralism. However, he reconsidered this position on intervention in later works. In the edited collection, *Arguing About War* (2004), Walzer adds an account of *jus post bellum* or justice

after war to his just war theory, and accepts that he is more willing to condone military interventions for gross human rights violations of life and liberty such as massacres and ethnic cleansing (2007: 251). He is also more willing to accept occupations and nation-building (Reiner, 2011: 178). These revisions to his position on nonintervention are supplemented further in edited collection, *Getting Out: Historical Perspectives on Leaving Iraq* (2009), where he argues for an ethics of withdrawal that takes seriously the dangers and safety of vulnerable people post withdrawal (Reiner, 2011: 191).

In 1980, Walzer was hired as a Professor in the School of Social Science at the Institute for Advanced Study (IAS) in Princeton, New Jersey. In 1986, he was made UPS Foundation Professor at the School which he held until 2007, when he became a Professor Emeritus of the Institute. He joined a small permanent faculty at the School that included the symbolic anthropologist Clifford Geertz (1970–2000) and the heterodox economist Albert Hirschman (1974–85), who together had developed an interpretive style that sought to bridge the divide between social science disciplines. Both were empirically oriented scholars who did not believe in grand theories or abstract models to explain human behavior, focusing instead on understanding the complexity, meaning, and consequences of human actions in collective contexts. Geertz was also a cultural particularist, who did not believe in human universals across cultural groups, and who developed a method of thick description to interpret cultural symbols observed while in use. The IAS, and in particular Geertz and Hirschman, are the last important influences on Walzer's work.

The cumulation and compounding of influences in his work, evident in his early books, is more apparent in some of his major works from his IAS period. This is shown in *Spheres of Justice* (1983), which is dedicated to his deceased father, Joseph, and acknowledges Judith Walzer, Howe, Nozick, Rawls, Geertz, and Hirschman among others, and refers to presentations and discussions at SELF and the IAS. His democratic socialism is clear in the book's purpose "to describe a society where no social good serves or can serve as a means of domination" (1983: xiv). The social goods analyzed in the book are illustrated using situated historical examples following the historical idealism of Beer and his colleagues at Harvard University. There is also an anthropological awareness of human culture and diversity reflecting Walzer's interactions with Geertz at IAS. The emphasis on interpreting 'to one's citizens the world of meanings that we share' (1983) further reflects the influence of Geertz and Hirschman's interpretive style and Geertz's cultural particularism. The topic of distributive justice also indicates the influence of SELF, particularly Rawls and Nozick, who each published major books in the early 1970s on the topic. The main influence, though, is Nozick who taught a course with Walzer at Harvard on Capitalism and Socialism in 1970–71 in 'the form of an argument,' with 'half the argument' expressed in Nozick's *Anarchy, State and Utopia* (1974) and the other half in *Spheres of Justice* (1983: xvii).

While protecting the human rights of life and liberty is the basis of *Just and Unjust Wars*, the distribution of social goods within different spheres of society is the focus of *Spheres of Justice*. These goods include: membership in the political community; security and welfare; money and commodities; office, work, and leisure; education; kinship and love; religion; recognition; and political power. The number and type of goods in a particular community depends on distinct meanings shared by its members based on their collective self-determination, with each good relatively autonomous in its sphere, with distributions between members of each sphere based on internal principles or standards of justice (1983: 10). However, there is not one 'distributive system that philosophy can rightly encompass' that would provide a single standard for just distributions across the spheres (1983: 4, 5). Instead, 'principles of justice' are 'pluralistic in form' and are 'the inevitable products of historical and cultural pluralism' (1983: 6). Balance between the spheres is meant to prevent dominance of one social good, and monopoly of a dominant good by a specific social group or coalition (1983: 11, 12). At the same time, ongoing struggles between groups and coalitions change the meanings of justice and injustice, and the distribution and balance between goods in a community (1983: 12, 13).

While it is a good that can be monopolized and made dominant, political power is 'the regulative agency for social goods generally' (1983: 15). It is "used to defend the boundaries of all distributive spheres, including its own, and to enforce the common understandings of what goods are and what they are for" (1983). The result is a regime of complex equality in which "no citizen's standing in one sphere or with regard to one social good can be undercut by his standing in some other sphere, with regard to some other good" (1983: 19). Democratic participation by community members as active citizens in the ongoing process of engaged argument and collective self-determination is the 'key to the equality of complex equality,' with each citizen 'equally entitled to persuade each other about how we should live our common life' (Reiner, 2011: 100). This societal pluralism extends the range of Walzer's pluralism to encompass ideologies; organizations; religious, ethnic, and national groups; and the international sphere of nation-states.

Walzer revised, added to or modified many of his positions in *Spheres of Justice* in subsequent books. *Interpretation and Social Criticism* (1987) develops the methodology of interpretation used in Spheres. It aims "to provide a philosophical framework for the understanding of social criticism as a social practice" (1987: vii). It also serves as a 'theoretical preamble' (1987) to *Company of Critics* (1988) which applies this perspective to the study of 11 social critics from the United States, Europe, and South Africa from the 1920s to the 1980s. It argues for a process of interpretation that 'accords best with our everyday experience of morality' (1988: 30), and addresses the issue of universalism and particularism. While moral prohibitions 'have been accepted in virtually every society' and 'constitute a kind of minimal and universal moral code' (1988: 24), these provide only a framework for community members to thicken through 'continuous conversation' into 'shared understandings' that develop into a 'moral culture' (1988: 25). Walzer adapts Geertz's concept of thick description here to distinguish universalist from particularist conceptions of morality, and to explain the process by which universal principles become particularist and plural through the continuous, shared conversations of people. While everyone is involved in the interpretation of shared morality, he prefers the 'connected critic' who is 'one of us' and 'who earns his authority' by appealing to 'localized principles' (1988: 39, 40). However, the

interpretations of connected critics have no special authority and must persuade others to prevail. This interpretational pluralism is an ongoing process since there is no single correct interpretation and 'the argument has no end' (1988: 49).

Thick and Thin (1994) extends the argument that there is a thin universal morality and thick cultures in which the meaning of common terms like justice or democracy become particular with each community (1994: 2–5). It is also an example of Walzer's explanatory pluralism accounting for the difference in his focus on 'thin' minimal, human rights in *Just and Unjust Wars*, and 'thick' meanings of distributive justice in specific communities in *Spheres of Justice*. *Thick and Thin* also provides an account of individuals as divided selves in terms of multiple roles, identities, and values (1994: 85). This individual pluralism is better suited for our complex, 'thickly differentiated,' culturally particular societies by allowing more opportunities to act on the various aspects of our divided selves in the spheres of society in everyday life (1994: 101–103).

Politics and Passion: Toward a More Egalitarian Liberalism (2004) is Walzer's most recent revision to *Spheres of Justice*. It focuses on complex equality within a 'domestic society' and critiques liberalism for not adequately accounting for the complexity of people's ordinary lives within a complex society (2004: 140). Its account of associational life does not acknowledge social group, cultural, political, and moral 'involuntary constraints' that many people willingly accept as obligations in their everyday lives (2004: 3–11, 20). Its belief that power is dispersed throughout society downplays 'categorical inequality' that systematically excludes dominated social groups from societal goods (2004: 33). This modifies Walzer's ideal of separated and balanced spheres that distribute goods through internal principles resulting in complex equality at the individual and group levels of society. Addressing this systematic inequality requires both liberal emancipation of individuals from excluded groups, and multicultural empowerment of these groups with the state providing the needed goods to take care of their communities (2004: 33, 37). This combination of emancipation and empowerment more widely disperses power throughout society, and addresses systematic inequality better than liberalism (2004: 41).

After the fall of Soviet Communism, Walzer became interested in the role of civil society movements in Eastern Europe. This is reflected in *Pluralism, Justice and Equality* (1995a), a coedited book with David Miller that includes chapters by critics and supporters of Walzer's theory of complex equality in *Spheres of Justice*, and Walzer's response to these including strengthening the roles of the state and citizen activities in civil society, and in the edited book, *Toward a Global Civil Society* (1995b). He defines civil society as "the space of uncoerced human association and also the set of relational networks – formed for the sake of family, faith, interest, and ideology – that fill this space" (2007: 115). Civil society encourages democratic participation by citizens in associational life, increasing their capacity for self-determination, while satisfying their diverse selves and need for sociability (2007: 123). He claims that the 'strength and vitality of our associations' is 'intimately connected' to the 'quality of our political and economic activity and of our national culture' (2007). Civil society helps to rebalance the dominance of 'market imperialism' and reduce unequal outcomes (2007: 125), becoming a central element in balancing the spheres in societal pluralism. However, "civil society, left to itself, generates radically unequal power relationships, which only state power can challenge" (2007: 129), using its "political power to redistribute resources and to underwrite and subsidize the most desirable associational activities" (2007: 131).

Walzer also became more interested in the relationship between civil society and multiculturalism, particularly in the American context, during the 1990s. *What It Means to Be an American* (1992) examines 'the politics of difference in the United States' (1992: 3). For Walzer, ethnic, religious, and national identities, not class, are the main group commitments across the world (1992: 57). However, he believes "ethnic pluralism is entirely compatible with the existence of a unified republic" (1992: 66) through nonethnic, civic citizenship and a very specific activist state. As in civil society, the state should provide resources through multicultural policies to ethnic, religious, and national groups to strengthen associational life; it should regulate cooperation between different groups to maintain a 'pluralist civil society' based on 'peaceful coexistence' (1992: 6, 7). While the state should not 'foster a particular identity' (1992: 77), it should help to create a unified national identity, for example, through a civics curriculum in the public schools that teaches the history and practice of democracy, including pluralism, in the United States (1992: 17, 18; Reiner, 2011: 172).

On Toleration (1997) continues the discussion of these topics from a conceptual perspective. Walzer argues toleration is made possible by "the peaceful coexistence of groups of people with different histories, cultures, and identities" (1997: 2) and that peaceful coexistence is "clearly an important and substantive moral principle" (1997: 2, 6). However, there are no authoritative moral conclusions that can be drawn from philosophical discussions of toleration, and no form of peaceful existence that is universally valid (1997: 1, 2). Instead, principles of toleration are 'relative to the history and culture of the people whose lives it will arrange,' although there is a thin universal morality of 'minimal coexistence' based on the rights to life and liberty (1997: 4). Based on historical case, he abstracts five 'ideal versions' of regimes of toleration: multinational empires, international society, consociations, nation-states, and immigrant societies (1997: 3, 14–36). At the end of the book, he returns to his goal to meld the best of liberalism, socialism, communitarianism, and other ideologies (1997: 112) into a coherent 'political creed' of democratic socialism (1997) While constantly debatable, this creed generates policies for practical action by committed public intellectuals and citizen activists to achieve through democratic persuasion of their fellow citizens. Multiculturalism in this case is 'a program for greater social and economic equality' that combines a 'defense of group differences and an attack upon class differences' through individual, community, and state action (1997: 111).

The impact of Walzer's work can be quantitatively assessed to a certain extent in terms of awards, recognition, and book sales. Thus, Walzer was awarded the Spinoza Lens in 2008, a prestigious biannual prize for ethics in the Netherlands. He was also recognized as the 61st most prominent public intellectual in 2008 by *Foreign Policy* and *Prospect* magazines (Reiner, 2011: 1). Furthermore, the combined sales of his book, *Just and*

Unjust Wars, approximately equal the total sales of all of his other books (Reiner, 2011: 176). It is more difficult to assess the qualitative impact of his work given his prolific output of books, chapters, articles, essays, and reviews over almost 60 years beginning in 1956. It is also difficult to assess given the range of his topics from war to equality, diversity, and Judaism, the almost continuous reassessment of his own beliefs expressed in his work, the number of significant influences and cumulative effect of these on his work, and the many social roles that Walzer has fulfilled in the family, as a member of the Jewish community, and in work as an activist, editor, professor, and public intellectual. This account of his divided selves suggest that Walzer's impact is more appropriately understood as differentiated according to the answer to the question: Which Walzer for what audience?

The differentiation of Walzer's work across topical spheres is also a product of his rejection of grand theories, and philosophers or others as self-proclaimed authorities. He reaffirmed this position in a recent interview stating "it is useful to have pieces of a theory, but big *meta*-theories more often produce arrogance and authoritarianism in the movement or the state" (Williams, 2012: 6). These pieces of a theoretical approach are evident in the different uses of pluralism in his work, ranging from ideological, organizational, ethnic, religious, national, international, societal, interpretational, explanatory, and individual. However, there is no 'grand' theory of pluralism in a single work that would serve as an introduction and as a focal point to his work. The theory of complex equality in *Spheres of Justice* with its societal pluralism is the closest to a grand theory that Walzer has published. Yet, even without a grand theory, the impact of Walzer's work can be assessed in a more direct, personal way: as an exemplar of a humble man, who no matter how right he thinks he is, allows others to be wrong, and tries to persuade them to his point of view, while not intervening unless life and liberty are at stake. In the long term, it may be that Walzer's impact is in the principle and practice of heroic noninterference as an ethical model to live a good life with others.

Wanting vs Needing

Abstract

Wanting (incentive salience) is a psychological process, triggered by rewards and their cues or imagery, which normally provides an 'oomph' that spurs motivation for objects of desire. Typically 'wanting' is in conformity with significant needs. But 'wanting' can sometimes dissociate from needs and from deliberative plans in maladaptive ways. Most dramatically in drug addiction, when amplified excessively by changes in brain reactivity, 'wanting' can have pathological intensity. Other impulse control disorders, such as gambling and overeating, may possibly share a similar compulsive 'wanting.' And even in ordinary daily life, occasional dissociations of 'wanting' from needs might occur. Selective surges in 'wanting' may explain why under these conditions, rewards can be 'wanted' much more than they are needed or even 'liked.'

Want versus Need

In a classic study of delayed gratification, Mischel and colleagues (Mischel et al., 1972, 1989) examined the ability of young preschool-aged children to patiently refrain from consuming a tasty marshmallow placed in front of them, when promised that if they could wait, a second marshmallow would additionally be received when the experimenter returned later. Some children succeeded in resisting the tempting marshmallow in order to earn the extra one, whereas others succumbed to the immediate temptation. Subsequent findings revealed that children who displayed the greatest amount of patience later went on to have better life outcomes as measured by SAT scores, educational attainment, body mass index, and other life measures.

What happens at such moments of temptation? What is the nature of the temptation process that self-control must wrestle with? Why is a marshmallow one can see and smell more difficult to resist than one in the next room? We suggest that one important psychological process in temptation is incentive salience, also known as 'wanting.' Incentive salience is typically triggered by encounters with reward-related cues (or related vivid imagery), and experienced as surges of motivation to obtain and consume the reward that can last even beyond the presence of the cues or imagery. Incentive salience is generated by brain 'mesolimbic' systems that react to reward cues, involving dopamine and other signals that converge on the nucleus accumbens. The intensity of the 'wanting' surge is determined by the reactivity of brain mesolimbic systems at the moment of cue reencounter. This motivation intensity may reach heights that become nearly compulsive if the brain systems are especially highly reactive, which can happen in certain states (e.g., in stress, emotional excitement, relevant appetites) and especially in some individuals (e.g., addicts). Incentive salience is an adaptive psychological response that is crucial to normal life. But sometimes it can go awry, in ways small or large, with consequences for well-being.

The ability to delay gratification in the face of temptation is thought to reflect the sensitivity of an individual's reward system. There frequently are moments of temptation in life for everyone, where temptations can sometimes drive individuals to act in ways that may not best fit their needs. The brain's reward system is designed to make people usually want what they need, but given the right conditions they are prone to wanting in the absence of any need.

Most commonly, intense dissociations between wants and needs may occur when brain reward systems and the attribution of 'wanting' (incentive salience) become hypersensitive. This can happen to moderate degrees temporarily in ordinary life under conditions of appetite, stress, or emotional arousal. Greater degrees of hypersensitivity can occur in more extreme conditions, the most dramatic case perhaps being drug addiction. This is referred to as incentive sensitization and results from repeated assaults to our reward system by addictive substances such as drugs of abuse, highly palatable foods, repetitive gambling, or even chronic stress. Following sensitization of their reward system, an individual may be more vulnerable to the magnetic properties of reward cues, such as the smell of brownies or coffee brewing, the sight of a regular watering hole or a needle for an addict, or the flashing lights of a slot machine in a compulsive gambler. All of these cues will trigger powerful wants that are often separate from an individual's needs, and require the exertion of regular cognitive control to maintain behavior on an appropriate course. In most individuals this may mean merely having a second brownie when you know one was enough, or having another drink at the end of the night. In recovering drug addicts however, this may mean undermining the intention to stay drug free and potentially lead to relapse.

Drug Addiction, Recovery, and Relapse

Addiction may provide a potent example of how incentive salience can rise to compulsive levels in some individuals. Relatively few individuals are susceptible to the degree of elevation in 'wanting' high enough to produce compulsive addiction under typical conditions. For example, most adults have used a potentially addictive drug at least once in their lifetime, if caffeine, alcohol, and nicotine are included in addition to illicit drugs. Yet most do not become addicts. For those who do, none of these drugs satisfy a true need except

when an individual is in pronounced state of withdrawal. Addiction is characterized by compulsive drug seeking, an impairment of social and psychological functions, and/or damage to one's health. Addiction typically involves overwhelming involvement with the addictive reward, a loss of control, and a narrowing of interests. According to a 2010 survey, less than 10% of the US population met the criteria for chronic alcohol or drug abuse disorder, and an even smaller proportion suffered from chronic addiction (Substance Abuse and Mental Health Services Administration, 2011).

A chief problem in treating addiction is chronic or repeated relapse among those who are trying to quit. Even after prolonged periods of withdrawal and abstinence, a high percentage of addicted individuals in treatment programs eventually relapse to drug-taking. For example, in the case of a study of heroin users, relapse rates to reuse after cessation were approximately 60% within 3 months and at least 75% within 12 months (Hunt et al., 1971). For this reason, drug addiction is characterized as a chronic relapsing disorder; relapse is the rule rather than the exception, and often occurs repeatedly.

There are three conventional reasons frequently suggested in psychology and neuroscience to explain addiction and relapse: (1) *Drug Euphoria* – that addicts resume drug-taking to experience the intense pleasure (euphoria) they remember the drug producing; (2) *Overlearning Habits or Predictions* – drug-taking becomes such a well-entrenched habit that relapse is almost inevitable, or that learning becomes distorted in other ways to create false predictions about drug rewards (Everitt et al., 2008; Hyman et al., 2006); and (3) *Withdrawal Escape* – that the withdrawal syndrome that accompanies the cessation of drug intake is so unpleasant an addict would do anything to stop it, and so relapse occurs as an escape from withdrawal (Koob and Volkow, 2010). All three of these explanations certainly play a role in relapse. However, we believe they are insufficient to explain the central problem underlying relapse in addiction, for several reasons.

First, drug pleasure or euphoria certainly accounts for the initial pattern of drug use and abuse, but may have more difficulty accounting for relapse as tolerance can develop to the pleasure. Even addicts who do not find their drugs particularly pleasant anymore may experience increases in drug craving that persist a long time.

It also has been suggested by some learning-oriented scientists that the repeated use of drugs creates a learning disorder, such as making drug-taking an overly ritualized habitual act or creating false expectations of exaggerated reward. Ritualization may be true of the act of drug-taking, but cannot explain the preceding flexible acts of drug seeking during craving. And there is little reason to believe that addicts mispredict the reward value of their drugs, or the consequences of their actions. Learned habits or mispredictions alone cannot account for the excessive motivational attraction of addiction.

Finally, many addictive drugs surely do induce tolerance (when drug is present) and withdrawal (when drug is absent). Withdrawal is typically described as an intense negative emotional state accompanied by dysphoria, anxiety, and irritability, and may indeed be a potent reason why many addicts relapse and take drugs, at least while the withdrawal lasts. Yet withdrawal is a relatively short-lived phenomenon, and decays substantially within days to weeks. By contrast, relapse frequently occurs even after withdrawal is no longer reported, and even in fully 'detoxified' addicts, months after 'recovery.'

In contrast to these suggestions, the Incentive Sensitization Theory (Robinson and Berridge, 1993) originally proposed an alternative explanation that can account for the persistence of relapse, and the independence of addiction from pleasure, withdrawal, or faulty expectations. It may also have applications to some addictions that extend beyond drugs, and proposes an explanation for the dichotomy that sometimes exists between wants and needs. The Theory proposes that relapse frequently occurs as a result of brain changes that lead to intense incentive motivation for drugs. These brain changes generate pulses of incentive salience or 'wanting,' often triggered by encountering drug cues, which may be experienced as feelings of drug craving or may even control behavior implicitly without need of strong conscious feelings. Craving occurs when the process of incentive salience (or core 'wanting'), mediated primarily by subcortical mesolimbic brain systems that use dopamine as an important neurotransmitter, is translated into conscious awareness. At its core, the motivation to take drugs is due to the overattribution of incentive salience to drug-related stimuli. It is important to note that incentive salience is a distinct psychological process from withdrawal and drug pleasure. In some cases, attribution of incentive salience to reward-predicting cues may make the cues 'wanted' as much as the reward itself, irrespective of whether the reward constitutes an actual need. Such cues become motivational magnets, sometimes prompting irrational behavior, such as interactions with the cue specific to those previously seen only during interactions with the reward itself (Davey and Cleland, 1982). As example of irrational cue attraction, crack cocaine addicts can be found inspecting the floor for a white speck that is more likely to be an ordinary pebble than crack cocaine, and can be attracted to pick it up, inspect, and put it in the pipe and even try to light or smoke the noncocaine pebble (a phenomenon that has been called 'chasing ghosts') (Rosse et al., 1993).

Incentive Salience and Utility

In applying incentive salience to daily life choices, it can be useful to consider such explanations in terms of forms of reward *utility* that are important to decision-making: predicted utility, decision utility, experienced utility, and remembered utility (Kahneman et al., 1997). All these forms of utility are critical in the process that determines whether a reward is truly needed, or if it is simply wanted. Predicted utility is an expectation of how much a future drug reward will be liked. Decision utility is the valuation of the drug manifest in choice and pursuit. Experienced utility is how much the pleasant drug is liked when actually taken. Remembered utility is the memory of how pleasant the drug was in the past. Experienced utility is considered the end point of the decision process. It is the state reached after successful attainment of a particular outcome, pertaining to the hedonic evaluation of that outcome. Experienced utility informs to some degree both remembered and predicted utility. However, other signals are needed in order for decisions to actually be made. The incentive sensitization theory suggests that only one of these, decision utility, of which incentive salience is one constituent, need to be distorted to create

a compulsive addiction. If decision utility fails to clearly distinguish between what is wanted and what is actually needed, then addictive and compulsive behavior is given the opportunity to proliferate, with behavior that is persistently guided by urges and cravings rather than cognitive goal-directed action.

Typically, decision utility is determined by predicted and remembered utility. However, predicted and remembered utility may fail to be a perfect representation of experienced utility, because hedonic memories can become distorted, such as when peak-end averages of a hedonic experience outweigh in memory the actual amount of pain or pleasure that was experienced (Kahneman et al., 1997). Drug addicts are also believed to often fail to accurately translate experienced utility into decisions (Bechara, 2005). In general, any distortion in memory or prediction that leads to faulty predictive utility will likewise affect decision utility, producing decisions that fail to maximize experienced utility of chosen outcomes.

However problems in excessive decision utility for addicts and some others facing strong cue-triggered temptations may remain even when their remembered utility and predicted utility for drug consequence are quite accurate. This is where there is a special role for incentive salience, because of the ability of brain mesolimbic systems to become especially highly reactive under some conditions (Berridge, 2012; Berridge and Robinson, 1998). Although 'wanting' typically coheres with 'liking' (hedonic impact) for the same reward, 'wanting' and 'liking' can be dissociated in certain circumstances and by some manipulations, especially those that specifically involve dopamine. Finally, 'wanting' can also be distinguished from learning and predictions about the same reward. For example, 'wanting' triggered by a Pavlovian reward cue can dramatically increase motivation for the reward, even if its previously learned value has not changed (e.g., in hunger, satiety, stress, or drug-related states). Abstinence from smoking for only 24 h can dramatically potentiate neural responses to smoking-related cues (McClernon et al., 2009). This also means that in instances where needs have been satisfied, wants may still occur, particularly when triggered by reward- or drug-related cues.

In this framework, incentive salience 'wanting' is a pure form of decision utility, which is distinct from other forms of utility and in some conditions can decouple from all the others (Berridge and Aldridge, 2008). That is, 'wanting' for an outcome is distinguishable from both experienced utility (hedonic impact or 'liking' the outcome), remembered utility of how nice the outcome was in the past, and anticipated or predicted utility of how nice it will be in the future. For incentive salience, under conditions of dopamine-related stimulation, situations exist where cue-triggered decision utility > remembered utility from the past, and similarly decision utility > predicted utility for future reward value. In other words, it is possible to addictively 'want' what is not expected to be liked, nor remembered to be liked, as well as what is not actually liked when obtained. All of these situations apply to rewards that are needed but become infinitely more problematic when they relate to rewards that satisfy no need and are purely wanted.

Such intense 'wants' may be triggered especially at particular moments, on particular encounters with addictive cues but not on other encounters with the same cues. According to the incentive sensitization theory of addiction (Robinson and Berridge, 1993), attribution of incentive salience to a reward cue becomes exaggerated in addicts due to mesolimbic brain changes that are very long lasting (Paulson et al., 1991). Exaggeration can happen because incentive salience, which makes up part of decision utility, always results from the synergy between two sources: previously learned associations about the reward cue and the current brain state at the time of cue encounter (Berridge, 2012; Zhang et al., 2009). In the case of needs, that brain state can be driven by hunger, thirst, or even salt deficiency, but where drugs are concerned, the presence of drug-related cues or small amounts of the drug itself can spur powerful wants in the form of craving.

How dramatically can raising brain mesolimbic reactivity make 'wanting' detach from, and soar above, memories or learning-based predictions of value? So much so that even a repulsive learned cue for unpleasant sensations can become suddenly and intensely 'wanted' via the activation of mesocorticolimbic circuitry. This can sometimes be useful and meet adaptive needs, which is why the psychological process and brain mechanism of incentive salience evolved. For example, we have shown that rats which learned a revulsion toward a Pavlovian cue for unpleasant Dead Sea saltiness, will on their first reencounter with that cue in a novel salt-need state activate their mesolimbic circuitry in a way that generates intense 'wanting,' instantly transforming the cue into an attractive and powerful motivational magnet that is jumped on and gnawed (Robinson and Berridge, 2013). While adaptive in that case, similar powerful brain transformations may be recruited to varying degrees by addictive drugs, other motivational consumption disorders, and even ordinary emotional states that heighten mesolimbic reactivity to reward cues (including marshmallows). This cue/state transformation helps define what it means to say that addiction hijacks brain limbic circuits of natural reward. Finally, different individuals may be differentially vulnerable to such mesolimbic transformations that generate such moments of intense 'wanting.' Fluctuations in the temptation power for cues, which illustrates the difference between decision utility and predicted utility, hinge on the current neurobiological state factors related to dopamine at the moment of cue encounter. In particular, incentive sensitization suggests that craving and relapse are magnified by a sensitized neural system (mesocorticolimbic dopamine and related systems), which can flip into a super-reactive mode under several conditions. Those include especially states of stress, or if a person tries to 'just take one' hit of their addictive drug (that primes mesolimbic systems to react more powerfully to cues), or in other emotional states that heighten mesolimbic reactivity. At such moments, ordinary stimuli, such as cues associated with rewards, are transformed into potent incentive stimuli, making them attractive and able to trigger an urge to pursue and consume their reward. Under these situations, an individual is the most vulnerable to expressing wants that are most distally removed from true needs.

This type of synergistic modulation of 'wanting' is not limited to addicts. Everyone has experienced at least moderate pulses of incentive salience in their lives that are generated by similar rules. For example, advertisements that pop up on a Web page may prompt the finger to click onto the product. The smell of food as you walk down the street may make you

suddenly feel quite hungry, even if you were not feeling that way moments earlier. But the smell of food as a cue is not constant in its temptation power: if you really have not eaten all day you might find the aroma extremely tempting, whereas you would not if you have recently eaten. The essence of incentive sensitization suggests that addicts encounter fluctuations like this in the temptation power of their drug-associated cues, but that their maximal peaks of temptation are much higher than other people are liable to experience in daily life because of the enduring sensitization of their mesolimbic systems.

The basic mechanisms of the excessive attribution of incentive salience to drugs and drug-related stimuli can even occur as a mostly automatic and unconscious process, creating urges to take drugs whether or not a strong subjective feeling of craving is simultaneously present. Such dissociation between acted-on motivation and confusing subjective feelings is what often renders the compulsive quality of an addict's own behavior astonishing even to him or her. Here, unconscious wants would have the ability to override our cognitive pursuit of needs, sometimes emerging as a sense of loss of control.

Only 'wanting,' not 'liking,' becomes sensitized and consequently more intense on its own, as addiction develops. That is because 'liking' or pleasure has separable, and more restricted brain mechanisms (Berridge and Kringelbach, 2013; Smith et al., 2010). Thus elevated 'wanting' can detach from normal 'liking.' For example, in animal studies, sensitization increases neuronal firing in pathways that code incentive salience as well as the behavioral ability of reward cues to trigger frenzied bursts of effort to obtain the reward (Tindell et al., 2005; Wyvell and Berridge, 2001). Yet sensitization does not increase 'liking' reactions that reflect the hedonic impact of the reward when it actually arrives. Similarly, in humans who are becoming drug-tolerant addicts, incentive motivation to take the drug can grow as they become addicted, so that a single hit of drug can provoke intense urges to take more, even if the person reports the dose of drug no longer gives as much pleasure as initially.

Other Forms of Excessive Wanting Beyond Drugs

Binge Eating and Food Addiction

Beyond purely drug addiction, consequent incentive sensitization may also manifest itself by food bingeing, pathological gambling, hypersexuality, and other compulsive motivations. Unlike drugs, food fulfills a bodily need, yet it can still be wanted to excessive levels. Overeating is a chief cause of growing obesity trends. Could exaggerated 'wanting' or 'liking' play a role in some individuals? Excessive hedonic reactions to food would magnify both 'liking' and 'wanting' above that of a regular individual, thus contributing to binge eating and obesity (Berridge et al., 2009; Davis et al., 2009). Alternatively, changes in 'wanting' alone could be responsible for overeating. Sensitization of mesolimbic dopamine systems by exposure to cycles of bingeing alternating with dieting has been suggested to occur (Avena and Hoebel, 2003a,b). Enhanced sensitivity of the mesolimbic reward system could attribute high levels of incentive motivation to the sights and smells related to food and drive excessive consumption, without necessarily producing comparable levels of 'liking' when the food is itself consumed.

A different set of problems may face some other individuals, who have been suggested to have elevated 'liking' as well as 'wanting' that drives binge eating and overconsumption, and possibly deserve the label of food addicts (Davis et al., 2009; Davis and Carter, 2009). Notably Davis and colleagues have found that certain individuals who are both obese and binge eaters are far more likely to carry both alleles for a gene that codes a gain of function for mu-opioids, and another allele for a gene that may be associated with higher binding for the dopamine D2 receptor. Together these genetic traits have been suggested by Davis and colleagues to combine to simultaneously increase 'liking' and 'wanting' for foods in a manner that strongly promotes binge eating and gives rise to addictive like features, including loss of control and relapse. This may be a rare example where 'wanting' and 'liking' increase in tandem, making it exceptionally hard to adhere to levels of food intake that conform to physiological needs. Similarly, it has been suggested that individuals who carry genes promoting elevated dopamine function might experience stronger cue-triggered urges in response to food cues, making them more liable to develop obesity (Campbell and Eisenberg, 2007).

Conversely, it has been suggested that anorexia nervosa, involving a failure to eat, is related to a reward dysfunction that suppresses the 'wanting' for food despite leaving the 'liking' portion intact (as well as developing an abnormal 'wanting' for body perceptions of self as thin) (Keating et al., 2012). This could be interpreted as a case of insufficient 'want' that fails to achieve the motivation required to fulfill basic needs.

Gambling

Gambling might also involve special recruitment of incentive salience brain systems. Uncertainty may especially promote incentive salience under some conditions, which mirror many of the hallmarks of gambling (Anselme et al., 2013; Linnet et al., 2012; Lobo et al., 2010; van Holst et al., 2010). It has even been shown that not knowing how hard one must work to be rewarded may even sensitize the brain in ways similar to addictive drugs (Singer et al., 2012). This may produce a further example of the dissociation between experienced or remembered utility and decision utility. Individuals sometimes seem driven by cues to gamble, in all cases at a global monetary loss, for only a moderate experience utility. It seems that despite a conscious awareness that, for example, slot machine gambling will repeatedly end with a loss, showing a cognitive awareness that playing will fail to fulfill any monetary need, players want to gamble, sometimes expressly to satisfy an urge to play. Compulsive gamblers may also show other addictions (Zhang et al., 2009).

Consumer Behaviors

Even beyond addiction, situations may arise in everyday life in which incentive salience becomes particularly high to induce moments of strong decision utility to pursue or consume an incentive. Consumer goods can similarly be strong incentives influenced by powerful cues. Some situational factors, like being

in a store, might possibly increase how much consumer goods are 'wanted' while the extent to which they are 'liked' remains unchanged (Litt et al., 2010). Purchasing a product without actually 'liking' the product sufficiently to make the purchase under normal circumstances is likely to induce regret. Accordingly, Litt et al. (2010) suggested that 'wanting' and 'liking' for consumer goods can be driven in opposite directions, almost mimicking reports of drug addiction. When people experienced failure in pursuing desired outcomes (e.g., a 5$ gift card), individuals showed increased willingness to pay for this reward, i.e., 'wanted' the reward more. However, these individuals also happened to 'like' the reward less in the sense that they were likely to more often trade it away for an equivalent prize (5$ gift card from a similar store). Such instances show how consumer goods can be wanted more than they are needed. In cases of excessive consumerism or for people who display hoarding behavior, motivation to possess becomes tantamount and need becomes entirely irrelevant.

Summary

'Wanting' as a process and incentive sensitization helps explain fundamental problems such as addiction and, compulsive pursuits, as well as more mundane temptations such as a dangling marshmallow. In such moments of temptation, cognitive needs and intentions may be set aside either momentarily or sometimes more permanently, to satisfy intense cravings for incentives that are often more 'wanted' than they are needed. Incentive salience operates alongside more cognitive processes of planning and goals that may be aligned to meet major life needs. Often incentive salience operates in congruence with those needs, but not always. When 'wants' and needs diverge, temptations can arise of varied intensities. While temptation can be controlled, that control presents a challenge. Even an addict remains in principle capable of resisting temptation on any single trial, but in practice is likely to succumb to relapse if required to encounter a series of repeated temptations.

Powerful levels of 'wanting,' often in the absence of equivalent 'liking,' are not restricted to addictive drugs. The incentive sensitization theory potentially provides an explanation for why consumer goods and certain foods can also become excessively compelling incentives. In turn, ever-present cues, such as those incorporated in advertisements, can trigger potent 'wanting' peaks that propel susceptible individuals toward overconsumption of material goods and addiction-like disorders such as binge eating or gambling.

War and Democracy

Abstract

This article is an attempt to discuss possible causal relationships between 'war' and 'democracy.' One can ask: What is the impact of wars on democracies – and what is the effect of a state's democratic nature on its behavior with respect to war? If we add the distinction between 'socialization' and 'selection,' we realize that four key questions arise. All four questions are discussed here on the basis of theoretical reflections taken from the history of social thought and with reference to contemporary developments.

A schematic breakdown of the key questions on the relationship between war and democracy shows that there are two possible arrows of causality to consider. What is the impact of wars on democracies – and what is the effect of a state's democratic nature on its behavior with respect to war? We can add to these familiar questions the distinction commonly made by sociologists since the reception of Darwin in the nineteenth century and expressed most succinctly by Talcott Parsons in *The Social System* (1951). This is the distinction between two types of possible effect – 'socialization' and 'selection,' the former referring to a process of internal transformation and the latter to the varying probability of survival in particular environments – and it gives rise to four key questions:

1. In a belligerent environment, are democracies more likely to survive because they possess unique strengths or are they more likely to be defeated by their less democratic opponents?
2. Do democracies have specific effects on the nature of armed conflict when they engage in it?
3. Do democracies have a greater capacity for peace than other sociopolitical orders or are there qualities specific to democratic societies that put peace at risk?
4. How do wars affect the inner workings of democracies? Do they promote internal processes of democratization or do they threaten these processes, as well as existing democratic structures?

The picture becomes more complex still when we factor in that we cannot use the term 'war' to imply that the entire spectrum of macrolevel violence is covered by conflicts between clearly defined states, states that in principle recognize one another. If we include civil wars and states' suppression or murder of sections of their own populations, then another question arises, namely whether democracies represent insurance against such violence or whether, conversely, such things as ethnic cleansing in fact represent the "dark side of democracy" as Michael Mann (2005) has argued.

A wealth of answers to all these questions can be found in the history of social theory. This does not mean that we have empirically well-founded knowledge on all these questions at our disposal – quite the reverse. The aim here is to present some key ideas on these questions from the history of our subject, relating them to contemporary realities in such a way that we end up with a reasonably clear overview.

Are Democracies Weak?

Given the events of the twentieth century, the first question is probably the easiest one to answer, namely whether democracies are bound to be outdone militarily by their nondemocratic competitors. This supposition was long considered highly plausible, particularly in Germany. In contrast to clear chains of command and highly centralized power, it inevitably seemed that the separation of powers and the complex, necessarily controversial, time-consuming democratic approach to formulating objectives and making decisions could never offer much competition. During World War I, the great sociologically inclined historian Otto Hintze argued, for example, that Germany could not afford to become a democratic republic because of its geographical position in the middle of the European continent. The idea behind this was that only states in an exceptionally secure geopolitical position such as Britain and the USA could in principle do without a standing army. As standing armies always required centralized state administrations and could easily become tools of repression in the hands of monarchs and other rulers, Hintze believed there was an affinity between absolutism and external threats on the one hand, and parliamentarization and a secure position on the other. This idea was then trivialized in anti-British polemics. The phantasm of the *Führerstaat* was so central to fascism and National Socialism that it went hand in hand – as in Hitler's view of America – with a suicidal underestimation of the USA. World War II brought a definitive end to the tendency to underestimate the Anglo-Saxon democracies' capacity for mobilization and staying power. During the Cold War, only a few concerned liberals (such as Samuel Huntington in 1957) suggested that democracies were fundamentally inferior, but not the liberals' opponents. Communist leaders generally expected capitalism to collapse as a result of economic crises and their own technological superiority. And of course they also laid claim to the democratic idea in order to legitimize their own 'people's democracies.' Attempts to resolve empirically the question of the robustness of democracies in war – the most important being the study *Democracies at War* by Dan Reiter and Allan Stam (2002) – conclude that

since 1816 democracies have won three-quarters of the wars in which they were involved. In fact, according to these authors, this success rate increases if we look only at wars begun by democracies; in this case – according to these figures – the success rate is no less than 93%. Dictatorships, meanwhile, lost 4 out of 10 of the wars they had begun. Even when attacked, democracies were more often successful than dictatorships (63 vs 34%). Both these figures and their interpretation are subject to dispute. If the democratic societies are also the economically and militarily superior ones, then their success is not necessarily due directly to the fact they are democratic. Particularly in light of the USA's immense power and leading role, simply finding data that allow us to factor these realities out is a very difficult task. The advocates of the thesis that democracies are more successful in wars reject this criticism by arguing that it reinforces rather than refutes their interpretation of the evidence. This is because they assume that democracies enter into a war of their own accord only if they seem assured of victory. This, they suggest, is precisely why the data reveal a disparity between opponents with respect to military and economic power. According to this interpretation, not only are democratic conditions no disadvantage in war, they are a positive advantage. A democracy tends to have an easier time subjecting the pros and cons of a war to public examination and learning from the war as it progresses than other forms of political order.

But this of course applies only under idealized conditions. Democracies are not immune to internal attempts to emasculate their characteristic forms of critical public examination of the reasons for war and war strategies. In this respect, American democracy in the lead-up to the ongoing war in Iraq was a case in point. Quite deliberately, the country's political leaders constantly changed their position on war aims (WMDs, terrorism, democracy, peace in the Middle East). Congress functioned as a site of argument only to a very limited degree, even in comparison to the British parliament. Major media, particularly television – but also the press, including the New York Times, which later practically begged for forgiveness – accepted official reports bordering on falsification. The media narrowed down the spectrum of rationally possible courses of action to the question of the 'how' of war against Saddam Hussein in such a way that there was almost no discussion of the 'whether.' The aim of the Bush administration's media management was to push a narrative largely detached from the facts: "the greatest story ever sold" (Rich, 2007).

It is true that the progress of the war laid bare the fragility of the reasons given for the war and the incompetence of the planning, but it was, above all, the lack of success that fueled shifts in the public mood. Since Max Weber, sociologists have known that all political orders gain legitimacy through military victories. This was the case as long as Hitler was victorious in war, and even in the case of Stalin the end of World War II brought him many more loyal supporters. Democracies have also become more stable as a result of military victory. But what happens if a democracy starts wars by largely abandoning democratic mechanisms and fails to bring them to a successful close? Will this lead to a reintensification of democracy or to the even more adroit bypassing of democratic principles?

Are Democracies Cruel toward Their Opponents?

Do democracies have specific effects on the nature of any armed conflict they may be involved in? From Rousseau to contemporary journalism, the argument has been made that democrats are not only as cruel as their opponents in wars, but in fact even more cruel. Interestingly, in the work of Rousseau this argument was anchored in a moralization of warfare. In his radical individualism, states are artificial bodies and war is a clash between these artificial bodies. As a result, we may only fight the opposing state in a war, but not its citizens. We have the "right to kill" the defenders of the enemy state "while they are bearing arms; but as soon as they lay them down and surrender, they cease to be enemies or instruments of the enemy, and become once more merely men, whose life no one has any right to take" (Rousseau, 1964: 18). But it is doubtful whether Rousseau can sustain this division between state and people. Especially in the case of wars between well-organized republics – in which the will of the public holds away – the distinction between state and people would be annulled. So we could legitimately annihilate the enemy population in order to win the war. Particularly in the case of warring republics, however, this would make it impossible to humanize war as Rousseau wished to do. Every citizen would become a combatant, making it impossible to distinguish between soldiers and civilians. His pedagogical novel *Émile* shows that Rousseau (1979: 481) was aware of this consequence. He put forward the hypothesis that because of citizens' patriotic identification with their state, the wars of a republic would be waged with greater cruelty than those of a monarchy. Tocqueville gave this idea an interesting new twist in his brilliant analysis of America. According to him, any democratic opening up of the armed forces, in other words the diminution of aristocratic privileges in society as a whole, and armed forces in particular, may make them more aggressive. This is because military performance is best demonstrated in war. As a result, there will probably be a greater readiness to engage in military adventures within an army based on the performance principle. In light of this, Tocqueville believed he could discern a gulf between an army particularly willing and able to wage war and a generally peace-loving democratic polity: "We thus arrive at this singular consequence, that, of all armies, those most ardently desirous of war are democratic armies, and of all nations, those most fond of peace are democratic nations" (De Tocqueville, 2007[1835/40]: vol. 2: 266). Tocqueville's thesis is surely too simple: It merely raises the issue of the socially representative nature of the armed forces and their built-in performance standard without really developing it further. But the argument inherent to this question cannot be lightly dismissed. This problem came into particular focus when the USA entered the World War in 1917, a step it justified with Universalist moral and legal arguments. Carl Schmitt referred here to the "turn to a discriminatory concept of war" (Schmitt, 2003[1938]), asserting that this development intensified war. If he is to be believed, it is easiest to limit the scope of wars waged without illusion exclusively in pursuit of various interests. But if those waging them have a sense of moral superiority and believe they have a mission and morally superior cause, all inhibitions fall away. This is because we are no longer dealing with a battle between opponents on an equal footing, but one

between good and evil, between the preservers of order and those who would threaten it. Like many other elements of his often daring arguments, Schmitt's assertion has proved amazingly tenacious and is still quoted regularly to this day, particularly in polemics against the missionary pursuit of foreign policy. But there is no empirical evidence for it. It is of course true that there is always a danger of merely using morality to disguise interests, and that even if we have a sense of moral justification, we must always weigh up carefully the appropriate means and expectable consequences. Empirically, though, the history of violence in the twentieth century certainly does not show that it was mainly the warring Western nations, couching their arguments in moral Universalist terms, that displayed a tendency toward unbridled violence – quite the reverse. In World War II, American troops tended to commit atrocities on the Japanese rather than the German front, and later in the Vietnam War. In addition to the momentum of unbridled violence, which explains certain massacres, unless we consider them part of a strategy (Greiner, 2007), it was racism rather than a Universalist sense of superiority that played the central role here. The same goes for the violent excesses of the colonial powers, as with the suppression of the Mahdist revolt of 1898 in Sudan by the British. This draws our attention to the enforcement of Western universalism through an ideology of civilizational or even racial superiority. In recent years, Mark Mazower and others have demonstrated (Mazower, 2006) how strongly the history of international law has been pervaded by an exclusionary deployment of the concept of civilization, according to which legal norms are held to apply only among the civilized, but not when dealing with 'barbarians.' Because they will supposedly deploy any and all means to achieve their aims, any means of combating them can be justified. This way of thinking may solidify – as in the case of colonialism – into enduring racism. But there is always a risk of such thinking as a result of the spontaneous or actively managed dehumanization of the enemy. We can see this dynamic of dehumanization at work everywhere – in attempts to justify the lawlessness of Guantanamo, in the refusal to allow that the motives of so-called terrorists are in any way comprehensible, and in the dynamics that led to the sadism of Abu Ghraib. But moral universalism entails a countervailing impulse that assails all particularism, whether of the long-standing or of newly generated variety. Conversely, Schmitt's antiuniversalism was from the outset devoid of any such impulse. This is why he idealized the supposedly limited wars of European history and threw in his lot with Nazi policies on Europe. Furthermore, from a normative point of view, the idea of increasing the scope for violence for moral reasons rests on mistaken reasoning. From such a standpoint, the only thing that would be dangerous would be the moralization of international politics without due regard for institutions and procedures. But this is not the aim of advocates of a Universalist morality. Their goal is to establish legal norms, and organs to enforce this law, on an international level. The prosecution of war crimes and crimes against humanity must be pursued in a lawful way. That American foreign policy in the run-up to the Iraq War was not really Universalist in approach was evident in the arrogant devaluation of existing forms of international conflict resolution.

Are Democracies More Inclined toward Peace?

So our interim finding is that so far democracies have shown specific strengths in wars and by no means act more cruelly than other states because of their democratic character. But are democratic states more inclined toward peace? This is the third of our questions. There was an intensive social scientific debate on this question in the late 1980s and 1990s, though not so much in sociology as in that subdiscipline of political science known as international relations. Unfortunately, dialogue between these disciplines is a rare event. For a time it looked as though a real breakthrough had been achieved here. This theory was traced back to a classical thinker of uncontested stature in the shape of Kant, and it appeared so powerfully corroborated by empirical evidence that we seemed to be dealing with one of those rare empirical laws in the social sciences. Now, a decade after its heyday, the self-assurance of the theory's advocates has dwindled markedly and there is no longer any consensus about its empirical corroboration. Once again I would like to present relevant arguments drawn from the history of theory, along with some of a systematic and empirical nature, though they cannot truly convey the richness of this debate.

As mentioned earlier, Kant's 1795 text *Perpetual Peace* was the key reference point for the debate. Here he argues that war itself contains an innate impulse that eventually leads to peace. His reasoning centered on the idea that all present states have a tendency to become republics, as this is the only way to legitimize power on a broad basis – thus putting in place the crucial preconditions for states to prevail militarily in times of 'wars between peoples.' But if republics proliferate as a result of their success in wars, states' international conduct will change accordingly. This is because republics are controlled by the people, and therefore have no interest in aggressive international adventures. Ultimately, thought Kant, it is the people themselves who have to pay the blood price of all wars. Kant did not claim that republics have a fundamentally greater propensity for peace than other regimes. This propensity relates solely to other republican states. In Kant's eyes, the reason for this is cultural. The peaceful and regulated resolution of conflict within a state gives rise to a culture of peace, which carries over to its relations with other countries. A zone of peace gradually develops – a zone of increasing cooperation between states and mutual trust. A worldwide confederation of states now begins to enter the realm of the possible, a confederation in which it is legal rules and no longer violence that regulate relations between states.

While Kant's text had a tremendous impact in the first few years following its publication, it was later largely dismissed. Often, it was remembered as little more than an example of naive reverie. But this was very unfair. Kant was no dreamer, and even the literary form of his text might have guarded against this misinterpretation; he wrote it as a draft agreement, and all the national rulers had to do in principle was sign it. Some scholars of war presented findings of this stripe during the Cold War, but little attention was paid to them, as they did not seem helpful in overcoming that conflict. Who at the time expected the imminent democratization or even implosion of the Soviet Union? But with the end of the Cold War and a wave of democratization in various parts of the world, the vision of

a new democratic and thus enduringly peaceful world order suddenly became the goal of leaders such as the first President Bush, as well as his successor Clinton and left-wing peace scholars. Critics of this thesis were mostly power-political realists who warned against the moralization of foreign policy.

But it would be misguided to view the thesis of a democratic peace as the only alternative to power-political realism. It is far more productive to draw conclusions in light of the inherent difficulties in corroborating this thesis. Most of its advocates agree with the realists, against a minority in their own camp, that if democracies are more inclined toward peace at all, this is true only with respect to other democracies and not in any general sense. This is by no means an insignificant qualification. It opens our eyes to a danger evident immediately after the appearance of Kant's text. As early as 1796, the young Schlegel pointed out that "there was still material left to wage war over" (Schlegel, 1796; in Batscha and Saage, 1979: 106), as long as despotic states existed. And Görres, a Jacobin in his youth, expressed this more pointedly in 1798 to the effect that he was in favor even of the violent "republicanization of as many despotic (regulative) states as the circumstances of time and place allow" (Görres, 1798; in Batscha and Saage, 1979: 168). Such 'messianic interventionism,' with its inherent propensity for violence, was not limited to German thinkers after Kant, but is also to be found in the work of others such as Thomas Paine. Tocqueville himself got to know democratic society – in America – as a highly expansive way of life. This led him to suspect that democracies could be kept stable only through an expansionary dynamic. This is not messianic interventionism, but does represent an expansionism specific to democracy. He used this argument to endorse the French colonization of Algeria in brutal and unqualified terms.

The credibility of the claim that this amounted to an empirically grounded social scientific law diminished upon closer inspection of the way in which it had been operationalized. Which states should be classified as democratic in the nineteenth century – in view of the fact that universal and equal male suffrage was so rare, let alone its female counterpart? It was near impossible even to define war and involvement in war. There was a clear tendency, whenever an example was put forward that proved the opposite, to define the countries involved as nondemocratic or dispute that the conflict in question represented a war in the first place. Theoretical and methodological consequences soon followed once scholars realized that constant reduction of the number of cases considered valid had led them down an argumentative dead end. Theoretically, the thesis was now expressed in relative rather than absolute terms. So now the claim was not that democracies never wage war on one another, but merely that they do so rarely and less often than other regimes. Methodologically, there was a turn away from comprehensive quantitative surveys of all wars and all democracies toward case studies. These have the advantage of helping us uncover the causal mechanisms that (supposedly) make democracies amenable to peace. We can distinguish a structural argument (control of the government by a populace unwilling to go to war) from a cultural one (negotiations in the absence of violence) in Kant's reasoning. But the structural argument had a weakness that was soon to deprive it of its plausibility after Kant. It was based on the idea that the common people are peace-loving and unmoved by aggressive sentiments or ideologies. The age of nationalism and great political ideologies sufficiently demonstrated the reverse. But the cultural argument, at which hopes of a solid theory were now inevitably directed, also suffered from a congenital defect. It would in fact have lent support to the strong thesis of an unconditional capacity for peace, though this is empirically untenable, rather than the qualified thesis of democracies' relative capacity for peace with respect to other democracies. So the debaters came to two conclusions. First, they recognized that countries' conduct is crucially determined by their perception of one another as democratic, and second, that Kant's notion of the republic is not identical to the notion of democracy and liberal culture. There is a great deal of empirical support for this perception-based argument, as it is always the presumption of trustworthiness that makes trust possible. This argument can be challenged by the fact that perception is not simply objectively given, but may be shaped by processes of definition. Power-political rivals are quickly labeled undemocratic by the leaders of democratic states as and when required, while useful allies are just as swiftly declared 'flawless democrats.' The classic example of such a process of redefinition occurred in connection with American intervention in World War I. In a number of studies, Randall Collins (1999), Ido Oren (1995), and I myself (Joas, 2003) have tried to show that prior to 1914 the German Empire was perceived as culturally advanced and by no means undemocratic in either the USA or Great Britain. It was only when relations deteriorated that Germany's authoritarian characteristics were emphasized and even Kant, Goethe, Beethoven, and Wagner declared pathological figures. For the war to be portrayed as a struggle between democracy and autocracy, from the February Revolution of 1917 at the latest Russia had to be stylized as a democracy and Germany as a special case of deviant modernization. In such contexts, the term 'democracy' is simply too sweeping. The task of sociology is to get closer to social reality beyond the mere attachment of labels to a political order while also investigating the role of the concept of democracy in the construction of antagonistic stereotypes.

The other argument, namely the distinction between liberal and nonliberal democracies, further qualifies the thesis of a democratic peace. If it is not the capacity for democratic control that produces a propensity for peace but rather a liberal culture of tolerance and individualism, then Kantian hopes of perpetual peace depend on the spread of this liberal culture rather than the democratization of the world. In this case, at least up to the present, this theory applies only to the West and essentially to the period since the end of World War II. But is it not possible that quite different factors – such as the tremendous affluence and hegemony of the USA, or European fatigue after two world wars – are responsible for the emergence of a zone of relative peace? Might not the long peace in fact be the cause of the triumphant march of liberal culture? The conclusion here is clear in a negative sense. It is not the case that democracies are markedly superior in terms of their capacity for peace. This is apparent even without factoring in new trends toward the diminution of democratic controls over the armed forces – through the outsourcing of military services to so-called private military companies, for example. The positive conclusion – as peace scholar Harald Müller rightly states – is

that we must "cast light on the specific circumstances in which democracy does in fact engender the peace-maintaining effects claimed for it" (Müller, 2002: 46). Empirically, this opens up the debate within international relations to historical sociology. Normatively, it opens up the debate to a concept of peace not founded on a single dimension of causality.

What Are the Effects of Wars on Democracies?

Kant was interested in the causal relationship between war and democracy (or republic) from both sides of the equation, though this has been paid little notice in the debate on the democratic peace. He had to be, because for him the possibility of establishing a stable "civil constitution" ("bürgerliche Verfassung") (Kant, 1977[1784]: 41) depended on achieving "a lawful relationship with other states." This brings us back to the first of our questions, concerned with the effects – beneficial or detrimental – of wars on democracies. As early as the nineteenth century, sociologists began to develop a wealth of theorems that assumed the existence of a spiral mechanism. There were optimistic and pessimistic variants. Herbert Spencer (1885: 557ff) was one of the optimists. He believed that industrial societies are more peaceful than military ones, and that the dissociation between military service and the status of citizen typical of such societies, in other words the professionalization of the armed forces, in turn strengthens individualism. Friedrich Engels' "Herr Eugen Dühring's Revolution in Science" ("Herrn Eugen Dührings Umwälzung der Wissenschaft (Anti-Dühring)") (1988[1878]: 204) presents a rather similar argument. In his view, the introduction of universal military service and advanced weaponry was driving the states of Europe to financial ruin while arming the workers and peasants: Here again, we have the assumption of a self-reinforcing mechanism leading to a more peaceful world. Interestingly enough, the pessimistic variant of this theory can be found in many forms, particularly in the history of American social science. Notorious social Darwinist, William Graham Sumner warned in 1898 that American imperialism was encouraging militarism and plutocracy and threatening American political culture. In the early days of World War II, Harold Lasswell (1940) set out the horror scenario of an impending "garrison state" in which the people are more or less entirely at the mercy of "specialists on violence." Most spectacularly, in the 1950s, C. Wright Mills advocated the idea that the USA in the twentieth century had broken with its anti-militaristic tradition and that an alliance had formed between economic monopolism and military bureaucracy, an alliance that had come to dominate the very interpretation of reality. He feared that this mind-set and these power relations made it impossible to prevent nuclear war.

With hindsight, however, it is clear that neither the optimistic nor pessimistic prognoses on the basis of these theories have been proved correct. Both variants of the notion of a self-reinforcing mechanism have proved overly mechanistic. It may seem astonishing, but empirically the optimistic predictions proved correct far more often than the pessimistic ones in the nineteenth and twentieth centuries. What Parsons called 'inclusion,' in other words the extension of civil rights to previously excluded sections of the population (blacks, women, young people), often occurred as a consequence of wars, as did the broadening of social rights. Conversely, as Paul Starr (2007) argues, the liberties so often curtailed in wartime were frequently regained once the war was over. Yet, these facts do not really lend support to the optimistic variant for two reasons. First, the causes of successful processes of democratization are quite obviously significantly more complex than it would appear in the simple image of a spiral of reinforcement. Even Spencer and Engels revised their thinking on this point, and we have every reason to take seriously the contingency of the success of democracy. The pessimistic variants at least teach us that wars are not mere interruptions of civilizational progress, but may be constitutive of entire eras, of new social and political structures. This applies in the case of successful steps toward democratization, but especially in cases in which defeat and destabilization enable dictators or totalitarian movements to seize power.

Second, there is no guarantee that the so far often beneficial effects of wars on democracies will persist. The optimistic interpretations are based on two tacit assumptions: that wars last for a limited time, after which, for example, liberties can be enhanced once again, and that they are dependent on the loyalty of large sections of the population, their readiness to support the war effort through reduced consumption, working harder, and perhaps even risking their own lives. But these conditions do not necessarily apply. Systematic attempts may be made to ensure that they do not. During the Cold War, Mills already feared that restrictions would be justified with no prospect of their removal in the foreseeable future. At present, the so-called War on Terror seems to be a textbook case of a war that can never be declared over. The title of the book, *The Forever War* (Filkins, 2007), alludes to this. The Iraq War was something quite new in terms of financing and mobilization. Despite its huge cost, it was accompanied by massive tax cuts, and military strategy there and in Afghanistan was geared toward the minimization of American losses through technological superiority and a military personnel whose composition in no way reflects American society as a whole. So the formerly inclusionary effects of war have now become improbable.

Abstract

This article explores the relationship between war and nationalism as it developed since the French revolution and the French revolutionary wars from the perspective of international political history. It shows how nationalism as a modern ideology changed the essence of warfare, while the relationship grew in intensity in the long gestation from the Napoleonic campaigns to World War I, reaching its peak in the heydays of totalitarianism between World War I and World War II. Totalitarianism is largely seen as an attempt to preserve the state's radical control over its citizens achieved under war conditions.

The postwar order created the conditions and the institutions for severing the symbiotic relationship between war and nationalism by focusing on interdependence, human rights, etc. However, the excesses of neoliberal globalization have curtailed the representativeness of political institutions, while fomenting instability, which may lead to a new assertion of nationalist conflicts and war. Finally, our traditional notions of war, nations, and nationalism are likely to change when dealing with the catastrophic impact of environmental degradation.

Introduction

While organized warfare has been taking place at least since the Bronze Age (Eckhardt, 1992: 170), nationalism is an entirely modern phenomenon, which can be ascribed back to the French Revolution (1789–99) and, occasionally, to the English Civil War (1642–51), and the American declaration of independence (1776). Because of their impact on both political legitimacy and warfare, the French Revolutionary Wars (1792–1802) are the most clearly identifiable chain of events inaugurating the 'special relationship' between war and nationalism as it shaped the development of the Western system of nation-states. In particular, Paris' introduction of the *levée en masse* (a term combining the meanings of 'uprising' and 'levy') on 16 August 1793 established mass conscription in the defense of the nation as a military model then widely emulated. Despite its uneven spreading, the industrial revolution also contributed to both warfare and nationalism, although the latter often proliferated among elites well before they embraced industrialism.

This article identifies the peak of this relationship in the period between 1789 and 1945, to which most space is therefore dedicated. The last sections briefly discuss both postwar developments and the coming challenges to this relationship.

From the French Revolution to the French Revolutionary Wars and the Napoleonic Campaigns (1789–1915)

As the French revolution degenerated onto a factional bloodbath, appeals to unity became nearly inescapable among ruling elites and quarrelsome Jacobins. After France entered into war (1792), a deeper cycle of conflicts began, so that international violence, rather than revolutionary violence, became the main unitary catalyst. According to the historian David A. Bell, the Battle of Valmy (20 September 1792) saw the first army in human history inspired by nationalism, as throngs of soldiers immolated themselves to shouts of 'Vive la Nation!'(Bell, 2008). Although victory was made possible by casual events such as bad weather, Jacobin propaganda promptly seized Valmy as a foundational myth, unleashing waves of enthusiasm and the belief that fighting in the name of 'freedom' would grant soldiers a sort of immortality and even invincibility. Bell identifies this as the 'first total war,' a concept usually associated with the trenches and the 'human waves attacks' of World War I, but already detectable with the notion of *guerre à outrance* emerged during the Franco-Prussian War (1870–71). At Valmy, for the first time, the sheer number of men ready to sacrifice themselves on the front line became decisive. The unprecedented 'enthusiasm' for mass death was only made possible by the Parisian elites' coherent effort to channel popular emotions by appealing to nationhood and patriotism as an organizing ideology. Despite, and possibly because of, fratricidal struggles among revolutionary elites, populism and patriotism were shared across the political–ideological spectrum. Thus, the first total war was also the first ideological war and the first nationalist war. It provided a further foundational myth to the first modern nation-state with the triumph of a new ideology linked to (positivistic) ideas of modernity and progress.

From July 1791, even before the war began, to July 1794, the French army became the target of a strenuous propaganda effort, with 7 million copies of various revolutionary journals distributed among high- and low-rank soldiers, although most of them could hardly read or write (Lynn, 1996). Mobilized around the sacred defense of *La Patrie* (the Mother/Fatherland), soldiers were hailed as the supreme expression of 'collective will,' while war was described as the finest of national virtues. Before the *levée*, volunteers were drafted in through an array of visual effects and media grandeur, often surrounded by a festival atmosphere punctuated by martial music. For urban elites, mass conscription became *de facto* a 'nation-building' device insofar as nationalism could emerge as the broader interclass ideology suitable to mobilize and control a largely rural population. "The first mass army depended ultimately upon a political revolution whose ideology, redolent of

nationalism, stressed the equality and community of all Frenchmen" (Posen, 1993: 83).

The emphasis on patriotic unity concealed and embellished deep ideological cleavages. This is how nationalism sprouted like a *deus ex machina*, providing the decisive strategic advantage and the common denominator of all ideological forces competing to act in the name of the Republic. Through war mobilization, Parisian riotous elites achieved unified support for what had become one of the most fragmented, ideologically splintered, and identity-fractured countries in Europe. For instance, insofar as he did not control the National Convention and the Committee of Public Safety, Maximilien Robespierre (1758–94) was opposed to war, which he intuitively felt as a potential distractive device through which 'antirevolutionary' forces could seize power (Robespierre, 2007: 30; Scurr, 2006). However, once in full control, he did not hesitate to pursue war further to consolidate his own supremacy. By merging culture, ideology, terror, and war at once, nationalism offered an impromptu combination of consensus and coercion, 'spontaneous' peer pressure and hetero-directed state repression. Although the Reign of Terror's bloodbath reached its peak after November 1793, when the threat of foreign invasion had receded, war abroad coincided with a dramatic increase in repression at home: systematic mass killing by government troops led some historians to identify the *Vendée* massacres (1793–96) as the first modern genocide (Jones, 2010: 6–7; Levene, 2008; Secher, 2003). The 'eliminationist' pattern was replicated, expanded, and 'refined' in other provinces and cities, like Brittany and Lyon. Together with the remoteness of the 'punished' regions, war provided the most suitable cover to carry out ominous crimes and abuses, which were hardly conceivable in pace times and in more dense urban setting.

The Napoleonic campaigns (1803–15) are sometimes seen as a continuation *of* the French Revolutionary Wars, but had an even more direct impact on the spread of nationalism while reinforcing its links with warfare: Napoleon Bonaparte's invasions not only created throughout Europe 'proto-national' institutions, which served as embryos for nascent nation-states, they also spawned unprecedented nationalist reactions against French occupation troops, like in Germany, Russia, Italy, Portugal, and Spain (Esdaile, 2004). The invasions inaugurated and fomented a downward spiral of intensifying aggressiveness, and a Darwinian race for the 'survival of the fittest,' so that a nation's continued existence seemed to be inseparable from expanding state power and strengthening its industrial and military apparatus. In turn, hostilities invoked increasing responses from the enemy, typically embossed by modernist and technocratic justifications.

Fatherland, Barrack, and School

The relationship between nationalism and war is underlined by the role of education as a facilitator and preparatory training for military life and war. Modern states aspired to the long-term molding of national consciousness through educational indoctrination and military mobilization. Of the two, the aim of mass education was more all-pervasive and long-term than mass conscription, ordinary citizens could welcome it more positively, despite heavy fines and even sequestration for nonattendance. The intimate connection between military service, patriotic coaching, and educational standardization is epitomized by Napoleon's 'nation in arms,' with its fusion of barrack and school: Napoleon was both hailed as the greatest military strategist and the 'education Emperor.' He implemented the standardization of the curriculum, instituted the *lycées* system, introduced school uniforms and examination procedures, reinforced the bureaucratic structure, and drafted newly stringent disciplinary standards. For Napoleon, a national elite could be formed by evenly applying military-like discipline and the principle of 'equal' opportunities to education, with copious largesse of newly established scholarships. The main goal was to forge a class of officials capable of administering his empire and leading his armies. The system sought to imbue young pupils with patriotic–militarist virtues and shape them into loyal servants of the central state. Napoleon's own military formation exerted a decisive impact on his confusion between the civic, educational, and military spheres (Colin, 1900).

The Westernization of the World: Nationalism and Conscription

Napoleon's project of a 'nation-in-arms' with its 'citizen-soldiers' was emulated across the ecumene with various degrees of intensity. Mass conscription was thus instituted in a host of countries of both the developed and developing world, from Prussia and Russia to Turkey and Japan, where it often merged with extreme forms of nationalism. In Japan, the new Meiji rulers (1870–81) transformed the *samurai* class system into the Imperial army through nationalism, education, and conscription (Harries and Harries, 1991). Conscription was one of the first measures taken in 1860 by the newly formed Kingdom of Italy: since the start it acted in tandem with the elementary school system to shape and structure a unitary Italian identity. Most of these governments saw conscription and militarization "as an instrument for developing social cohesion and political docility of the masses" (Bond, 1986: 32).

Pax Britannica, Industrial Development, and Empire Building (1815–1914)

The period spanning broadly from Waterloo to World War I, and particularly from 1870 to 1914, is often described as an era of peace and stability. However, just as continental empires collapsed, colonial empires expanded, while some state elites consolidated their grip on power over their rivals. Nation-states strengthened their control over citizens through the twin ideologies of modernism and patriotism, while intensifying the colonial scramble for the unspoiled. War and destruction were simply being exported beyond European borders and, by the late nineteenth century, an unrestrained *laissez-faire* economy had induced a series of 'late Victorian Holocausts' (Davis, 2001), including artificial droughts and floods in which millions perished. Linda Colley noted, "the profit and the price of this hundred-year partial European peace was unprecedented Western, and especially British, freedom to concentrate on global empire. In 1800, the European powers, together with Russia and the United States, laid claim to some 35 percent of the globe's total land area. By 1914 … [their] proportion of the globe … had risen to 84 percent" (Colley, 2002: 311). In

ideological terms, racism accompanied empire building just like nationalism propelled state making, as the two sides of the same coin.

Franco-Prussian Militarism

Strategically located between Prussia and imperial Britain, France was able to combine extreme imperialism and radical nationalism. In a fierce emulative competition, France and Prussia built powerful armies, bureaucracies, and industries. The Franco-Prussian War (1870–71) exerted unprecedented pressures to discipline and assimilate their respective populations, making ordinary people more conform to state directives and control.

Engaging in grandiose project of nation-building and social engineering, official nationalism acquired the capacity to produce that very 'self-disciplined subjectivity' necessary for the state to exert control both within and outside official institutions. This made possible broader forms of organizational discipline, and finally the participation of the masses into industrialized warfare. In a kind of domino effect, the fierce rivalry and mutual emulation between France and Prussia heralded a new era of intense, European-wide.

The Franco-Prussian military model spread across the globe but spared parts of the West, like the Iberian Peninsula, the British Isles, and upper Scandinavia. King Gustavus Adolphus of Sweden (1594–1632) introduced much earlier uniforms and regiments-based conscription districts in Sweden and Finland in which enlisted peasants replaced mercenary soldiers, so that military historians attribute to this important change, the Swedish victory in the Thirty Years' War (1618–48). Britain's imperial makeup turned the navy, rather than the army, into the key military force (Kiernan, 1998): Still in 1850 only about 105 000 armed personnel could be defined as military: that was "less than a third of the size of France's military at that time, less than an eighth of Russia's, and smaller even than the army of Prussia which possessed no colonies at all" (Colley, 2002: 312). Significantly, England/Wales was also one of the last places in Europe to adopt compulsory education (1880). Thus in Britain, "the army never became the school of the nation," but simply functioned as a rite of passage to adulthood, 'making men' more than making British men (Showalter, 2010: 142). This contrasted with Prussia, where the "military service was the precondition not only to full manhood, but also to full citizenship" (Berger, 2008: 620). However, just like in Prussia and France, war became a nation-builder since the British wars with Catholic France drove the distinct Protestant denominations into a closer union, reminding them of what they shared (Colley, 1992). In other respects, and until quite late, the British Empire did not follow the continental drift toward army aggrandizement and mass conscription.

Pupils into Soldiers: Expanding the Franco-Prussian Model

In 1880, France's minister of education, Jules Ferry (1832–93), introduced a set of sweeping reforms to impose compulsory, 'nonclerical' (*laïque*) education, which aspired to nationalize the masses through nationalist indoctrination by raising the public profile of the army. School reforms included courses in military exercises, gymnastics, needlework (for girls), and the actual replacement of religion with the cult of *la Patrie*. Eugene Weber describes the pedagogical catechism imposed throughout the *Hexagone* calling for the child's "duty to defend the fatherland, to shed his blood or die for the commonweal, … to obey the government, to perform military service, to work, learn, pay taxes and so on. At the very start of school, children were taught that their first duty was to defend their countries as soldiers …. Commencement speeches recalled this sacred duty in ritual terms – our boys will defend the soil of the fatherland. The whole school programme turned on expanding the theme" (Weber, 1976: 333). All disciplines were harnessed to this goal: history, literature, geography, and civic education. However, in terms of acculturation, by 1896, the army had proved to be "an agency as potent in its way as the schools" (Weber, 1976: 302).

In reality, after the *defeat* in the Franco-Prussian war, such developments were no longer uniquely endogenous: the nationalist stress on the education–military linkage mimicked developments in rival Prussia. For Peter Paret, "French adopted from Prussia not only true conscription … and the modern general-staff structure, but also the collaboration of the elementary schools and the conscript army to teach nationalism to the masses" (Paret, 1993: 49). The Franco-Prussian mutual contaminations expanded tangentially beside the army into other organizational and bureaucratic areas. Prussian developments were in turn a response to previous French threats and invasions: In 1813, Frederick William III "embarked upon a military mobilization that, for the first time, extended the obligation, and opportunity, to serve in war through all levels of Prussian society. Within the framework of the Revolutionary and Napoleonic eras, the Prussian *Erhebung* … was the movement that came closest to capturing the dynamism … of the French effort twenty years before" (Moran, 2003: 3–4). In other words, conservative Prussia followed the footsteps of revolutionary France, which in turn began a cycle of emulative competition, so that the roles were soon reversed; whereas, France was the initial model for export and even though Prussia had turned into a military state already before the French Revolution, Prussia became the apprentice who outdid the master, turning itself into the military and bureaucratic model to be imitated across the Europe and Asia, including in France.

Similarly, schools elsewhere acted as indoctrinating institutions. Thus, in Japan, primary and secondary schools operated to coach students for the imperial army, while teachers were trained in military barracks (Harries and Harries, 1991). In Turkey, the 'military-nation' based on education became 'foundational myth of Turkish nationalism' (Altõnay, 2004). One decade after France's defeat by Prussia (1871), "one could neatly perceive the notion of a Spartan-style education, entirely devoted to patriotic adulation and where the school became the antechamber of the barrack" (Girardet, 1953: 164). Propaganda through schooling and mass media became essential in the dissemination of militarism and was the key in the process:

> In the 1870s … nearly every French family became acquainted with the nature of army life. The darker aspects of barrack life were pushed into the background; what mattered above all was to prepare for the

> imminent war of revenge against Germany. Officers marked in black the frontiers of the lost provinces on maps of France, and soldiers ending their service often presented a bust of 'Alsace in tears' to their company commander.
>
> Bond, 1986: 35

While conscription was highly unpopular in some areas, with various anticonscript revolts both before and after Napoleon's times (Aaslestad, 2012; Forrest, 2012; Planert, 2012), soldiers' memoirs describe military service in highly commendable, praiseworthy terms (Bond, 1986: 35). The army's popularity was largely founded on the persisting myth of the 'nation-in-arms' as appeared during the late revolutionary period and then regulated by Napoleon (Forrest, 2009). "Prior to 1920, there was no serious discussion of conscientious objection in France. *Insoumis*, rebels and insubordinates, and *réfractaires*, draft dodgers, were a serious problem for the government at times" (Levi, 1997: 186). It is also possible that nationalism exerted a mobilizing function before soldiers joined their battalions and regiments, serving more to tie up civil society to the military, while justifying both military spending and human sacrifice.

The army provided a deeper and faster emotional impact on conscripts than compulsory education could exert on pupils – particularly in wartimes. School took much longer to shape loyal citizens than the drastic, strongly centralized, and hierarchical barrack. Isolation from family and friend, punishment, drill, and round-the-clock propaganda yielded more drastic results than the deeper river's flow of half-day classes.

Class was also an important factor. Through decades of propaganda, schooling, centralization, and bureaucratization, French peasants had incorporated a humiliating sense of class inferiority and often desired to remove the stigma associated with rural mores and illiteracy (Weber, 1976). For some of them, economic incentives for joining the army were significant at a time when rural life was disintegrating, state centralization pressed on, and massive taxation exacted a heavy toll on ordinary citizens. Despite widespread resentment against various forms of state intrusion and repression, the idea that the *Patrie* was being victimized and its soil violated awakened powerful patriotic sentiments. Ordinary citizens were taught to see the soldier as the supreme expression of the collective will, condensing the finest of national virtues: "War itself became an homogenizing experience as soldiers and sailors represented the entire nation and the civilian population endured common privations and responsibilities" (Tilly, 1990: 116).

War, Industry, and Nation: The Egalitarian Impetus

Industrialization and militarism, particularly when supplemented by nationalism, shared the mirage of equal relationships, underpinning new social relations characterized by invocations to 'egalitarianism,' which in turn concealed simultaneous interchangeability and hierarchization. Political cohesion was pursued first within the barracks, then within society at large, while the latter was being radically reshaped by industrialization. The mass army was possibly the most 'egalitarian,' yet the most hierarchical of the major modern institutions; while the rigidity of the chain of command remains inexpugnable, an army can only work on the basis of equal duties, rights, and behavior of its low-level ranks (only within the prison the new *combination* of hierarchy and egalitarianism yielded possibly more appalling human costs). Due to practical reasons, emerging modern armies experienced first and most forcefully the demand for cultural standardization and recruits' sameness. For instance, the U.S. army anticipated desegregation before the heydays of the civil rights movements, Fascism enrolled Italian peasants on the basis of the egalitarian promises, both symbolic (military comradeship) and tangible (pensions, special rights). This 'egalitarian' emphasis in times of war was shared by authoritarian, totalitarian, and democratic systems. In this way, dissent could be controlled through unprecedented, and otherwise unattainable, forms of conformism. But conformism also led to extermination, as replaceability does not value individual life and human uniqueness. In the process, European states led the way by "building up fearsome coercive means of their own as they deprived civilian populations of access to those means," relying mostly on capital and capitalists to reorganize coercion (Tilly, 1990: 68–69). Their impact was so far-reaching that a whole global order emerged in its image.

In the social sciences, "there is virtually no disagreement that the eruption of war almost instinctively increases in-group solidarity and national homogeneity," although it is likely that "macro-level solidarity and group homogeneity exhibited in times of violent conflicts originate outside of these conflicts … (and) homogenisation is a complex process that requires a great deal of long-term institutional work" (Malešević, 2010: 179–180). In fact, before war could complete its task of bureaucratizing and militarizing society, preparations for war had already hard-pressed citizens toward greater forms of homogeneity. But war itself contributed to wiping out many local cultures in all of the belligerent countries, while contributing to the enemy's cultural obliteration. For Eugene Weber, it was the experience of World War I, which proved decisive in diluting local attachments (Weber, 1976).

World War I

State-building, the cultivation of patriotism, colonial aggrandizement, economic expansion, heavy industrialization, and the unprecedented advance of technological progress led to uncontrollable military buildup, which finally exploded with World War I. Industries, economic welfare, and military arsenals expanded until everything short-circuited under the 'European apocalypses' of 1914–18.

Rapid industrial development meant that for the first time peasants could move in larger number to the cities leaving behind millennial traditions. A powerful and influential class of new riches emerged, which often embraced war, nationalism, and modernity with similar enthusiasm and greed. In many consolidated nation-states, like Italy, Germany, and France, modernists and ultranationalists became the most prominent advocates of war, including poets like d'Annunzio and Apollinaire, and art entrepreneurs like Marinetti (Conversi, 2009).

Before the conflagration, Leo Tolstoy (1828–1910) understood well the destructive linkage between nationalism and war:

> To free people from those terrible calamities of armaments and wars, which they suffer now, and which keep growing greater and greater, we do not need congresses, conferences, treaties, or tribunals, but the abolition of that implement of violence that is called government, and from which originates all the greatest calamities of men. To abolish the governments only one thing is needed. It is necessary that men should understand that the sentiment of patriotism, which alone maintains this implement of violence, is a coarse, harmful, disgraceful, bad, and above all, immoral sentiment.
>
> Tolstoy 1901, 1905: 157

This bitter commentary would remain unheeded and submerged by the more vociferous noise of patriotic war mongering. Interstate competition was measured not only in terms of technological progress, but also in the application of new technologies to the practice of war. For instance, the cavalry had remained the key unit until 1916, when war compelled armies to replace horses and cavalrymen with tanks and technically trained drivers, codrivers, gunners, radio operators, and specialist mechanics (Diamond, 2003), therefore amplifying and deepening bureaucratization. In terms of citizens and education, most states continued to further their goal of building homogenous communities in which school and army played a conjunct role in fomenting extreme patriotism and a quasi-religious cult for the Fatherland. The deification and divinization of the state, which first manifested itself under Robespierre, became the new 'normal' throughout Europe, as it was perfected and magnified by Fascism and Nazism.

The Peak of Nationalist Homogenization: From World War I to World War II (1914–45)

In Charles Tilly's words, the modern nation-state's yearning for homogeneity and control spawned 'the most bellicose century in human history' with about 275 wars, 115 million deaths in battle, and over 115 civilian deaths during the whole century (Tilly, 1990: 67). However, these data are still 'optimistic' because they exclude hundreds of millions and more killed by the state, through policies of genocide, politicide, 'classicide,' starvation, population transfer, economic manipulation, and war-related diseases (Mann, 2005). Moreover, "until World War II, more victims of war died of war-borne microbes than of battle wounds" (Diamond, 2003: 197). Tilly (1985) famously describes the modern state as a racket organization built on the taxation of uprooted, terrorized citizens, who were thus offered military 'protection.' More specifically, "the military played a prime role, influencing both the state apparatus and other organizations including, at a later date, business firms. For it was to a large extent in the military sphere that administrative power in the modern guise was pioneered" (1985: 113).

Nationalism, War, and Genocide

The linkage between war and genocide is so deeply established among scholars of all disciplines as to appear indissociable (Markusen and Kopf, 1995). In fact, the two have been defined as the 'Siamese twins of history' (Jones, 2010: 48). There is further consensus that interstate wars provide the ideal circumstance for carrying out atrocities which would be unthinkable in peace times (Bartrop, 2002; Fettweis, 2003; Levene, 2005; Melson, 1992; Shaw, 2003). Under the aegis of total war, pressures toward ethnic and cultural homogenization reached their peak. When the Anglo-French allied forces landed in Gallipoli in 1915, Turkey's military authorities began a 'securitization' campaign against the entire Armenian population, whom they perceived as the West's 'fifth column.' "What turned a war crime into a genocidal act was the context of total war [….] that translated deportation swiftly into the mass slaughter, abuse, and starvation of an entire ethnic group potentially troublesome to an authoritarian regime at war" (Winter, 2003: 208). Under siege by the 'West,' Turkey's elites ended up imitating the West. As a consequence, their military nationalism bred a 'culture of hatred' that demonized Christians and non-Turks. Bartov's (1996, 2001) work on Hitler's war in the east anticipated much of this war-centered approach as the Shoah was also carried out beneath the curtains and under the strains of war.

Fascism, War, and Nationalism

The relationship between war and nationalism, militarism, and patriotism reached its apogee under Fascism. After the calamities of war, the short-lived interwar hiatus was soon thwarted by the rise of Fascism with its futurist political religion, totalitarian symbolism, and a program of radically remaking society (Gentile, 2003). Totalitarianism can be described as a continuation of the state of war (Keegan, 1999; Mondini, 2006). During the war, European, American, and Asian political, military, and cultural elites had experimented an extraordinary control over their societies through mass mobilization. They were generally keen on preserving this power. Most importantly, all-pervasive war censorship was not limited to the war front, but had engulfed the whole of society, and therefore it was never completely lifted after the war. Moreover, the choir of propaganda, chants of victory, and patriotic rhetoric were continued. Despite the enormous sufferings, the cataclysmic destruction, and the obvious strategic errors that cost the lives of thousands, none of these were debated (rater than celebrated) at length, except within marginal sectors of society whose voice could not be heard as widely as necessary. Moreover, the anarchist movement had been annihilated by the war, when most anarchists turned to nationalism, socialism or died. Religious and socialist organizations, which had tried to articulate programs founded on peace-building, had scarce access to the mass media. In short, the war had emboldened elites and these generally had no intention of surrendering the unprecedented control over society they had achieved. In Italy, where an antiwar socialist and Catholic opposition was relatively vocal, both mainstream and fringe media continued their bellicose propaganda. A broad spectrum of public opinion became convinced that Italy's 'sacrifice' had been in vain, since the 'perverse' postwar international order had not accomplished the realization of the nationalists'

maximalist-irredentist goals, in particular the seizure of Istria and Dalmatia. The creation of Yugoslavia and the treaty of Versailles (1918) had been a blow to Italian nationalists, eager to control both shores of the Adriatic. War veterans imbued by expansionist nationalism played a key role in forming the political atmosphere, which propelled Benito Mussolini into prominence. Fascism itself emerged from outside the military sphere; but, once seized power, it promoted increasingly stringent alliances with military cadres. In turn, post-World War I military elites embraced Fascist ideology to fight against antipatriotic 'decadence' and the 'ingratitude' of ordinary Italians (Mondini, 2006). Contrary to Germany, compulsory draft (*leva obbligatoria* or *naja*) had been kept unchanged in Italy since the early days of the unitary state. The Nazis reestablished conscription in March 1935, emboldening the Third Reich's triadic relationship between militarization, nationalism, and mass industrialization.

Postwar Era and Globalization (1945–Present)

The new postwar international institutions and military alliances (like NATO), as well as regional federations (the EU) became an effective way to overcome international conflicts and divisions, so that war and nationalism could be increasingly disjointed and divorced. As we know, the Cold War (1948–89) had frozen most ethnonational conflicts, while threatening a nuclear Armageddon. After the Cold War, the eruption of localized ethnic clashes and regional wars showed that some of these had remained latent. However, other conflicts may have resulted from the rapid meltdown of the old system and the unmediated passage from late Soviet authoritarianism (or Yugoslav benevolent one-party rule) to a regime of wild economic liberalization and the adoption of international rules emanating from outside Europe (IMF, World Bank).

Since the 1980s, neoliberal globalization had been weakening state institutions, a decay and lack of control has been made visible by the interlocking 2008–12 financial and banking crises. Savage neoliberalism has corroded democratic and representative institutions throughout the world, establishing an unprecedented influence of giant multinational corporations and organized crime over the political affairs of nearly every single country. This power reconfiguration also reinforced specific potent institutions within existing states, amplifying bureaucracy, compressing cultural functions, and expanding repressive areas like policing and surveillance. The triumph of 'free-market' ideology has been so complete and devastating that, for the first time in human history, the use of financial capital(s) lies beyond the control of any human actor or institution, let alone the state. In other words, the bulk of free-flowing, boundless financial capital no longer performs an economic function. However, state power did not surrender its monopoly of tax levy and coercion within its territory – and has indeed increased the incarceration of citizens and noncitizens. Nationalism is no less significant now than before, but its relationship with both the state and the military has deeply changed.

On a more positive note, the rise of the doctrine of human rights shifted the focus on individuals and nondominant groups allowing many submerged voices to express themselves by lifting the veil of censorship. In this way, conflicts could be prevented and successfully terminated through consociational or other arrangements, which did not require secession or threaten state breakup, therefore pointing to the possibility of the nation-state.

Future Challenges

It is perhaps too early to assess the impact of unregulated globalization and its likely relationship with new wars, some alimented by the persistence of state nationalism, others by the rise of nonstate nationalism. An area which will not fail to produce groundbreaking research is the relationship between anthropogenic climate change and conflict, including war and nationalism. Against the backdrop of mass human displacement, global emergency may call for a universal supervising body, but crucial decisions may still take place within the hidebound confines of state arenas. Sooner, rather than later, these may include addressing highly taboo questions, like whether or not top carbon dioxide emitters might need to offer shelter to thousands, possibly millions, of environmental refugees. Although these and related issues have been kept at arm's length from the political agenda, they are likely to generate heated public controversy once, and if, released to broader sectors of the public opinion. The rise of higher barriers to stem free human movement lead to an exponential growth of mass policing and surveillance, leading in turn to unprecedented measures of mass expulsions, which may in turn feed extreme violence both by and against the state (Zimmerer, 2014). Worst-case scenarios adumbrate the collapse of entire systems, with those layers weakened by neoliberal globalization, like health and education, falling first. Once climate change begins to hit more dramatically core countries like China and the United States, a descent into international chaos may well push the world into a state of perpetual war alimented and toughened by nationalism. But many predictions are destined to fail, as eco-environmental issues are always complicated by the intrusion of capricious, volatile, arbitrary variables, like uncontainable epidemics and other climate-related health issues. A new relationship between war and nationalism is likely to emerge through a new geopolitics of 'securitization' as sketchily described in this final section.

Conclusions

Dying for the 'fatherland' may not be a contemporary fixation: Horace's epigram *Dulce et decorum est pro patria mori* ('It is sweet and good to die for one's country') expressed a similar mandate during the time of Augustus, the founder of the Roman Empire. What makes the difference with modern times is a superimposed multilayered ideological apparatus, whose upper layer is constituted by nationalism – with various intermediate layers like egalitarianism and

the faith in progress subsumed in it. Although bureaucratization and centralization predated the French revolution, politics and warfare changed forever once infused with nationalism. A wider project of mass self-abnegation and sacrifice could only be conceived by political elites in a post-1789 scenario.

Key to the nation-state's war effort has been its capacity to secure the willingness of its able-bodied citizens to die for a 'higher' ideal. Such power of life and death over most of its population, previously unthinkable, could only occur when nationalism allowed ordinary citizens to visualize the nation as a unified, organic body, the defense of which demanded individual sacrifice.

The second essential element was 'replicability' or replaceability: despite the cult of patriotic heroes, no individual was unique enough not to be fully replaceable by another individual like him. All this was made possible by nationalism's ability to conceal new hierarchies of power behind a rhetoric curtain of egalitarianism. Replicability was largely founded on a previously established stress on national homogeneity encouraging conformism, uniformity, obedience, peer pressure, cultural standardization, and fear of criticism, while conflating nation, ethnicity, and culture. Although these have been systematically cultivated in peace times through nationalism as a mass-mobilizing ideology (Malešević, 2010), it was during the war, and through the war experience, that they could shape society at a deeper level while removing all traces of constructive dissent. Therefore, World War I provided rulers with an opportunity to practice totalitarianism before its 'lessons' could be systematically applied by fascism and communism. In other words, totalitarianism manifested itself first in the trenches as an 'ancillary' aspect of the relation between war and nationalism.

State-builders were often obsessed with shaping the character, virtue, and manners of their citizens. Barrack and school continuously overlapped: the army served to inculcate the values of patriotism and the education system served to prepare the youth for army life. Whenever war and education were joined, nationalism would provide the ideological foundation underpinning the entire bureaucratic military apparatus. The entire armor of human and technological advantages acquired during the prewar period and the Belle Époque through unprecedented accumulation, military growth, free-market expansion, and interstate competition was ultimately unleashed in World War I.

Despite our self-assuring confidence that the postwar order somehow protects us from repeating the tragedies of the past, new and more devastating crises quite possibly loom ahead. The environmental crisis, with its trail of wars, displacements, hunger, epidemics, economic meltdown, and health disasters, may put an unprecedented pressure on existing institutions by spawning new unforeseeable relationships between war and nationalism.

Abstract

Recognizing that war and terrorism are inherently geographic, we aim to highlight the expanding geographies of war and terrorism. We believe that all-things-military are increasingly permeating the everyday and everywhere. The blurring of 'militarized' and 'civilian' space and the overlap of military technologies and everyday life is a distinctive feature of contemporary society. The objective of our article is to posit an emphasis on critical geographical understandings of war and terrorism by examining the embodiment of war and terror, the nexus of 'nature' and 'war,' the shifting 'place' of war and terror, and the forwarding of peace geographies.

Introduction

The history of geography's engagement with war, militarism, and (more recently) terrorism is long and embattled. As both Mamadouh (2005) and Black (2005) detail, academic geographers have participated in many ways to both the study – and promotion – of war. Operating largely in a context where war was conceived as both 'natural' and 'necessary,' many geographers used their expertise to advise policy makers and military planners (Mamadouh, 2005). Moreover, geographers contributed to the formation of foreign policies which often justified the use of military intervention as acceptable and, indeed, indispensable. This is seen, for example, in the early writings of prominent geopoliticians, including Friedrich Ratzel, Rudolf Kjellén, Halford Mackinder, and Karl Haushofer.

The geographic contribution to war has not gone unchallenged, as exemplified in the remarks of Yves Lacoste, who laments that *la geographie, ca sert, d'abord, a faire la guerre.* (Geography serves, first and foremost, to wage war. Wisner (1986: 212).) Peter Taylor (2004), likewise, sardonically writes that "God invented war to teach Americans geography." Geography, from such a position, is seen as Mars' handmaiden (Wisner, 1986; Cloud, 2002; Barnes, 2008; Kobayashi, 2009; Loyd, 2012). Recent critiques of both warfare as 'natural' or 'necessary' and the broader 'military–industrial–academic' complex have argued that traditional military geographies are linked with geographical determinism that supports and safeguards the sovereign power and territorial integrity of the state (Barnes, 2008). Wisner (1986: 212) is blunt in his assessment, stating that "the reality of geography is that its methods have been used for a long time by the military for targeting places and people." Consequently, numerous geographers have advocated for a more 'peaceful' or 'pacific' geography (Pepper and Jenkins, 1983; Megoran, 2010, 2011; Inwood and Tyner, 2011).

Given that war – and conflict more broadly – is inherently geographic, regardless of one's position, it should come as no surprise that the literature on geographies of war (and now, terrorism) is vast. As an initial read of the literature, it is possible to classify geographic studies of war into three broad approaches: 'traditional' military geography, spatial analytical, and 'critical.' The first has the longest history and is most associated with the subfield of 'military geography.' Here, the focus in on the interactions of *geography* (narrowly defined) and military operations, campaigns, and battles. As Palka and Galgano (2005: v) explain, "Military geography is the application of geographic information, tools and techniques to military problems." Historically, much of this literature addressed either geography as a facilitating or limiting condition to military operations (cf Winters et al., 1998; Harrison and Passmore, 2008) or as a source of conflict and territorial disputes (cf Diehl, 1991). Research along this vein continues, as some geographers have called for a greater application of geographical techniques, such as spatial analysis using geographic information systems to inform both our empirical documentation and understanding of war and terrorism (Siebeneck et al., 2009; O'Loughlin et al., 2010; Laygo et al., 2012) but also, more proactively, as counterterrorism tools (Beck, 2003; Shroder, 2005; Sui, 2008).

A second dominant approach – with strong connections with international relations and political science – employs quantitative methods and spatial analytic techniques in an attempt to analyze the location and dispersion of war and terrorism (cf Mandel, 1980; Most and Starr, 1980; Houweling and Siccama, 1985; O'Loughlin, 1986; Kirby and Ward, 1987). In part, this trend has been spurred by changes in the nature of conflict, namely, the shift from predominantly 'international' wars to 'civil' wars. According to O'Loughlin (2005: 85), more civil wars began in the 1990s than in any other post-World War II decade; moreover, not only are civil wars becoming more commonplace, these conflicts are also lasting longer and are more destructive in their consequences. The salience of geography (and spatial relations more specifically) has greatly informed the theoretical and empirical understandings of civil wars. The scholarly study of civil wars has been largely dominated by large-scale quantitative approaches; these have highlighted the *intrinsic* geography of civil wars, and especially the diffusion of conflict and the importance of spatial proximity to conflict. As O'Loughlin and Raleigh (2007: 495) identify, "one of the most important predictors of whether a country will experience a civil war is whether its neighbors have internal strife." Variously termed 'the spatial lag effect' or 'contagion,' this understanding of conflict is predicated on the observation that "countries are frequently involved in a complex nexus of conflict as wars ebb

and flow across borders due to the sanctuaries offered by neighbors, the placement of rebels in areas occupied by sympathetic minorities, the actions of refugees to undermine the forces that caused their flight, and the access of extraterritorial bases to external supporters and sources of income" (O'Loughlin and Raleigh, 2007: 495).

The quantitative modeling of civil wars has not gone unchallenged, however. Many geographers in particular have cautioned against the uncritical use of the contagion metaphor, nothing that such an approach may too readily elide into a staid geographic determinism (Tyner et al., 2011: 3). Consequently, recent work indicates a move to better conceptualize "how interactions between governments and non-state actors give rise to violence rather than to focus exclusively on the attributes of one actor [or state] in isolation" (Gleditsch and Ruggeri, 2010: 300).

The critique of spatial determinism inherent in many quantitative studies of (civil) wars highlight a third dominant approach to geographies of war and terrorism, this being a 'critical' approach. As Woodward (2005: 720) explains, critical studies seek to understand the "wider geographical imprint on militarism and military activity" (Woodward, 2005: 720). Consequently, the recent proliferation of critical geographies, coupled with a greater interface with other disciplines, has stimulated a more comprehensive – and theoretical – engagement with geographies of war and terrorism. Accordingly, it is not only an epistemological challenge to traditional approaches; it is also an attempt to broad the field; to address heretofore unexplored connections between 'all-things-military' and 'geography' (here defined as both topic and discipline). Although wide in scope, critical geographic approaches to war, terror, and militarism are most often forwarded by those working in the subfields of critical geopolitics and feminist geopolitics (Dowler and Sharp, 2001; Cowen and Gilbert, 2007; Bernazzoli and Flint, 2009, 2010; Dowler, 1998, 2012). Here, the "geographic logics and imaginations undergirding war, geopolitics, security, and reconstruction … have been subject to extensive criticism and theoretical elaboration" (Loyd, 2012: 477). In part, this trend has been motivated by the pervasive, ever-expanding 'war on terror' (Tyner, 2005, 2007; Ingram and Dodds, 2012) and the profuse militarization of society (Woodward, 2005, 2013; Gregory and Pred, 2007; Megoran, 2008; Farish and Vitale, 2011). Critical approaches have also been concerned to study not only geographies of 'war' but also (as discussed below) geographies of 'peace'; these efforts have sparked considerable debate on the definitions and meanings of both 'war' and 'peace' as well as the relationship between these two concepts (Kirsch and Flint, 2011).

Such a preliminary overview calls attention to the fact that as the conduct – and location – of conflict shifts, so too does the geographic study of war and terrorism. For example, recent military conflicts in Afghanistan and Iraq, coupled with the seemingly never-ending 'war on terror' has sparked considerable debate over the temporality of militarized conflict, that war (broadly conceived) has become an enduring feature of the twenty-first century. For Gregory (2011), however, war has become a prominent feature *everywhere*. From the administrative divisions of the earth into military spheres (e.g., the expansion of the United States' military command to cover all areas of the world), to the shadowy *battle-space* of cyber wars, it becomes glaringly obvious that war, terror, and militarism are pervasive. Indeed, feminist geographers (especially) have argued that the militarization of the everyday is central to the extension of state power into the daily and, even intimate, interactions of its governed population (Dowler, 2012: 490; see also Cowen, 2008). In this article we emphasize the expanding geographies of war and terrorism. We take our cue, in part, from the recent work of Derek Gregory and his articulation of 'the everywhere war.' We concur that all-things-military are increasingly permeating the everyday, everywhere; and that there has been a blurring of once distinct areas of 'operation,' between 'military' space and 'civilian' space; and that the overlap of military technologies and everyday life is a distinctive feature of contemporary society.

The Embodiment of War

A guiding principle of our article is to emphasize the *embodiment of war and terror*. It is necessary to not lose sight of the lived dimension of war and terror; that all manner of flora and fauna – and not just 'humans' – have been and continue to be affected (Slim, 2008; Tyner, 2009). As Loyd (2009b) remarks, "war is not healthy for children and other living things." In fact, geography's turn toward the everyday within the context of militarism is in part a reaction to the changing 'nature' of warfare (Ramonet, 2004; Kaldor, 2006; Brooker, 2010). For example, if one considers the totality of armed conflicts that occurred during the late twentieth and early twenty-first centuries, approximately 20 million people were killed and 60 million wounded in declared wars, civil wars, and other forms of mass violence; upward of 80% of these casualties were 'civilians' (Slim, 2008). Such a grim tally sheet highlights that categories previously and uncritically conceived as discreet and distinct are anything but.

No longer confined to 'traditional' or 'conventional' battlefields, warfare in the twenty-first century is all-encompassing. Indeed, war is no longer defined simply as a major armed conflict between states, but rather includes 'low-intensity' conflicts, 'stateless' wars, and 'dirty wars.' In parallel fashion, an entirely new arsenal of euphemisms have concocted in an attempt to minimize the destructiveness of warfare: 'smart-bombs,' 'precision war,' 'bloodless combat,' and 'collateral damage,' to name but a few. In critique of these developments, feminist and critical geopolitics in particular have significantly expanded how geography (as a discipline) approaches war and terrorism and, specifically, have forwarded greater engagement with the 'embodiment' of militarized conflict (Dowler, 1998, 2012; Dowler and Sharp, 2001; Hyndman, 2004, 2007; Fluri, 2009).

Feminist approaches, in part, seek to understand the complex relationship between macrolevel geopolitical policies, practices, and processes with that of the 'everyday.' More specific to geographies of war and terror, feminist perspectives identify, analyze, and critique the formation of various constructed subjectivities at scales usually excluded from conventional understandings of war and terrorism (Dowler, 2012). Both traditional military geographies and spatial analytical

approaches, for example, are often conducted at the national scale and make use of massive aggregate data sets; such approaches tend to provide a disembodied narrative that renders the production and relations of everyday life invisible. Moreover, feminist accounts have called attention to the emotions and embodiment of warfare, to the horrors and ugliness that are often (deliberately) hidden from view. As Griffin (1992: 11) writes, "we can speak about the airplanes and the kinds of bombs. We can even number the dead. But the actual dismemberment of bodies must only be hinted." Feminists and other critical geographers have refused to remain silent, providing embodied accounts of war and violence in contrast to detached, emotionless military histories, or heroic and overly virile glorifications of war (Tyner and Henkin, 2014).

Nature and War

The nexus of 'nature' and 'war' has long been a stalwart of geography. Traditionally, geographers have engaged in what has been described as a 'terrain-and-tactics' approach (Woodward, 2013). Here, the emphasis is directed to understanding how physical geography influences the conduct and context of military operations. Both topography and weather, for example, have long been studied as inhibiting factors that may alter the course of battle. Nature, so conceived, has been something to be overcome and controlled.

More recently geographers have sought to disentangle the complex relations between 'nature' (or, alternatively, the environment) and conflict. As Le Billon (2005: 217) explains "competition over natural resources has figured prominently among explanations of armed conflicts, from Malthusian fears of population growth and land scarcity to national security interests over resources defined as 'strategic' because of their industrial or military use, such as oil and uranium." Research, consequently, has examined the salience of both resource 'abundance' and resource 'scarcity' toward the generation and continuation of armed conflict (Homer-Dixon, 1999; Le Billon, 2001, 2007; Pelosi and Watts, 2001; Le Billon and Cervantes, 2009). This work has proved catalytic in the development of 'environmental security' studies (Dalby, 1992, 2009).

The interface of conflict and the environment is not limited to the presence or absence of resources. Considerable research has focused on the impact of climate change on 'national security' and the potential for armed conflict (Barnett, 2003; Barnett and Adger, 2007; Nordås and Gleditsch, 2007; Gleditsch, 2012). As Barnett (2003: 7) summarizes, climate change "poses significant risks to the livelihoods, culture and health of many millions of people in many different social and ecological and contexts"; such risks are not limited solely to the potential flooding of small island states, but may also include altered climate systems, potentially leading to famine and outbreaks of disease.

Geographers have also directed attention to the impact of both violent conflict (narrowly conceived) and militarism (more broadly) on the landscape. On the one hand, geographic research has documented how the rise of an industrial militarism, as exhibited by the use of landmines and cluster bombs, chemical weapons, and depleted uranium, has left a distinct – and lethal – imprint on the landscape (Wilson, 1988; Hupy, 2006; Davis et al., 2007; Hupy and Schaetzl, 2008; Tyner, 2010; Hupy and Koehler, 2012). Much of this work has adopted a critical perspective, noting that the military detritus of warfare continues to pose health risk to both people and the environment years after the violence has supposedly ended. On the other hand, geographic research has documented (and often critiqued) the production of militarized landscapes (Woodward, 1999, 2001, 2013; Pearson, 2012). This is seen, for example, in the study of military installations (Yamazaki, 2011), training and proving grounds (Watts, 1998; Woodward, 1999), sites of weapons testing, and places of military occupation (Weizman, 2007). A subfield of this literature has engaged in the debates over the 'benefits' of military installations, arguing that such landscapes are beneficial to environmental conservation and preservation (Westing, 1992; Watts, 1998; Havlick, 2007, 2011). Military installations, it is argued, ward off rampant industrialization and urbanization while simultaneously providing refuge to wildlife and plant life. Critics counter, however, that these studies divert attention from the larger environmental impacts of militarization and also obscure the incredible destructiveness of warfare (cf Sanders, 2009).

The Place of War

As the form and function of warfare and terrorist acts change, so too does the place of conflict itself. The increased prevalence of 'stateless' wars has, for example, irrevocably altered our understanding of war, violence, and conflict. 'New' wars are not only fought with new technologies; they are also fought on new terrains. Stephen Graham (2004, 2009, 2010, 2012) and Kenneth Hewitt (1983, 2009), in particular, have forwarded a reworking of both military geography and geopolitics to account for the destruction meted out against cities. Subsumed under the term 'urban geopolitics' this literature has directed attention not only to the targeting of civilians living within urban environments, but also to the deliberate targeting and destruction of cities as a military objective: *urbicide*. Urbicide, on the one hand, entails the deliberate annihilation (killing) of the material, built environment (Coward, 2004, 2008; Fregonese, 2009, 2012; Hewitt, 2009; Ramadan, 2009). Here, violence directed toward cities should not be viewed as 'secondary' or 'collateral' to the targeting of civilians and military personnel; rather, the violence must be seen as a practice of intentional annihilation of the cities themselves (Hewitt, 2009). From this perspective, cities are targeted because of their symbolism as concretized in architecture, but also because cities denote a particular (and presumed 'immoral') way of life. On the other hand, as Coward (2004, 2008) argues, urbicide also entails an attack on plurality; of the perceived cosmopolitanism exemplified by urban areas; in short, an attack on heterogeneous existence. From this vantage point, the destruction of cities is also a destruction of the possibilities of heterogeneity.

Beyond the changing 'terrain' of war and terror, geographers have also considered what we may call the 'immateriality' of militarism. Here, connections are made between the high-tech militarism of both armed conflict (e.g., cyberwar) and the everyday. Louise Amoore (2009), for example, forwards the concept of 'algorithmic war.' Intimately associated with the ever-expanding and never-ending 'war on terror,' Amoore (2009: 50) highlights the emerging geography of securitization and militarization of everyday life; she notes that "from the remote sensing to bodies on a railway platform, to the securing of identity via biometric algorithms, or the profiling of risk at the airport, the practices of the war on terror exceed any clear distinction between military/civil/commercial spheres." She (p. 50) concludes that "what we are seeing is a stitching together of the mundane and prosaic calculations of business, the security decisions authorized by the state, and the mobilized vigilance of a fearful public" (see also Amoore and de Goede, 2005; Amoore, 2006, 2007; Katz, 2007).

Peace and War

Geography as an academic discipline has a long history of peace-related research. Two early efforts include *The Geography of War and Peace* (Pepper and Jenkins, 1985) and *The Quest for Peace: Transcending Collective Violence and War Among Societies, Cultures and States* (Vayrynen et al., 1987). In part, the promotion of more peaceful geographers was in response to the specter of nuclear annihilation. More recently, geographers have critiqued not only the naturalness and necessity of war (Kobayashi, 2009; Loyd, 2009a,b, 2011, 2012; Gregory, 2010; Koopman, 2010, 2011; Ross, 2011; Williams and McConnell, 2011), but have also promoted a more normative vision of geography as an academic discipline (Megoran, 2008, 2010, 2011; Inwood and Tyner, 2011).

Such efforts have not been easy. As Williams and McConnell (2011: 927) highlight, "our understanding of what peace looks like, and how to research it, remains underdeveloped and analysis of its complexities and contradictions problematically lacking." Indeed, considerable discussion has centered around the politics and contestation over the 'meaning' and 'definition' of peace; this work has been spurred, partially, out of a recognition of the false dichotomy between 'war' and 'peace' as well as 'violence' and 'nonviolence.' Drawing inspiration from Galtung's (1969) influential separation of 'direct' and 'structural' violence, many geographers have destabilized the epistemological foundations of a range of artificial, socially constructed binaries, including but not limited to war, peace, violence, nonviolence, conflict, and postconflict (Kirsch and Flint, 2011; Ross, 2011; Loyd, 2012). Flint (2011: 31) accordingly calls for an approach that views the spaces of 'peace' and 'war' as intertwined; he suggests that social relations are basis of construction of both and concludes that instead of discrete categories, it is more productive to think of a continuum of social settings in which power relations and political differences always exist, but in varying degrees of consensus and nonviolence compared to disagreement and violence. Much of this work has, subsequently, drawn attention to the ways in which such false dichotomies fetishize the unremitting processes of the 'production of violence' under the current mode of global militarization (Farish and Vitale, 2011).

For Williams and McConnell (2011: 929; see also Loyd, 2012), it is necessary to understand peace as a social and spatial process, such as "shifts attention towards issues of power and politics and opens up questions on contingency, agency and embodiment …. Subsequently, the spectrum of violence and non-violence is exposed for investigation and peace revealed to be a highly differentiated landscape." By extension, Springer (2011, 2012) has challenged geographers to consider 'violence' also as a process. For Springer (2012: 138) "to treat the material expression of violence only through its directly observable manifestation is a reductionist appraisal" and "ignores the complexity of the infinite entanglements of social relations." It is more appropriate, therefore, to conceive of violence not as 'thing' or 'event' or even 'act' but rather as a process; violence as *moment* implies *momentum*. In other words, the imposition of political-economic structures designed to 'make life' are carried forward with a momentum far beyond the initial act. Violence conceived as such therefore redirects attention toward those actions and relations that are hidden from empirical observation.

Those scholars working in the areas of peace have enlarged the discussion to address other forms of conflict (and terrorism) that have traditionally been neglected in the geographic study of war and terror. Both feminist and critical geographers, in particular, have highlighted the violence directed toward (especially) women's bodies – as manifest, for example, in the geographies of intimate partner violence and rape (Katz, 2007; Fluri, 2009; Tyner, 2012). This research has, by extension, documented how the violence of sexism, racism, classism, genderism, ableism, ageism, homophobia, and xenophobia – to name but a few – continue to be legitimized through the production of militarized and normalized geographical imaginations. As Loyd (2009a: 865–866) concludes, "to understand who is made most vulnerable where and how socially produced harms are naturalized discursively and materially, it is necessary to theorize specific economic, political, and social relations of oppression and domination and how they articulate (or intersect) in particular historical, geographic moments."

Abstract

In defining war, this article explores the origin and historical development of armed aggression from the earliest human societies to the present. The fact that war is a relatively recent invention in the span of human existence, arising with complex societies, suggests war as neither a biological imperative nor integral to the human condition. The many forms war takes, from ethnic conflict through conventional militaries to guerrilla warfare are considered in order to understand the nature and culture of war. The twentieth century has been the bloodiest in history, and this piece examines the relationships between violence, society, and the exercise of power that help explain this. The changing philosophies and practices of war over time and society show war to be a complex constellation of economic, cultural, and existential, as well as political factors. The various theoretical approaches to war, from those characterizing premodern societies and the rise of the modern state to the present are discussed. In concluding, the future of war, and the new directions theory might take in best understanding war in the aftermath of the 11 September 2001 attacks, are considered.

Sun-tzu, the famous Chinese military expert, began his book *The Art of War* with the words "Warfare is the greatest affair of state, the basis of life and death, the Way (Tao) to survival or extinction. It must be thoroughly pondered and analyzed." These words, 2500 years later, still hold true: war has grown more deadly, and more damaging to human existence.

In the twentieth century alone, over 250 formally declared wars took over 100 million lives. Undeclared wars, including political repression, communal violence, and genocide took millions more; for example, between 50 and 100 million people have been killed by forces and citizens of states in the twentieth century because of their sociocultural and ethnic belongings. If we expand the definition of war to include such armed conflicts as gang warfare, 'the war on drugs' and, more recently, 'the war on terror,' casualties figures rise, though accurate statistics are not available on these forms of violence.

On entering the third millennium, one-third of the world's countries were engaged in some form of political violence. Whether these conflicts are called war or not often depends more on political rhetoric than on an accepted definition of the term. In addition, approximately two-thirds of the world's security forces use human rights abuses to control their populations. The victims tend to label this violence war or dirty war, while the state tends to classify this as defense or counterinsurgency.

The world has not always been characterized by such high levels of violent warfare. Wars today are longer in duration, more deadly, with visible as well as invisible linkages crisscrossing the globe, and kill higher numbers of civilians than wars of preceding centuries. The reasons behind war and the ways in which it is waged change across cultures and time, leading anthropological observers to talk about 'shadows of war' (Nordstrom, 2004), a cycle of 'global war' without any certain ending (e.g., Whitehead and Finnström, 2013), and of globalized 'war machines' feeding on an underprivileged but increasingly flexible and truly transnational post-Fordian work force (e.g., Hoffman, 2011). Also, the changing characteristics of war demonstrate that organized violence is not a fixed and eternal fact of biology, nor an inescapable feature of a Freudian psyche, but a human practice guided by norms of behavior and codes of conduct situated in cultural and economical values.

Defining War

Neither the two world wars, nor the more recent 'world war' raging in the Democratic Republic of the Congo, nor the several hundred local and regional wars since 1900 have brought us closer to a shared understanding of war. Most scholars accept a basic definition of war as the deployment of violence to force opponents to comply with one's will. Many argue that the number of so-called battle-related deaths is the defining aspect of war, others, especially anthropologists, emphasize the need to include also the consequences of structural violence to the understanding and definition of war. Either way, war is organized, group-level, armed aggression rooted in hierarchies of dominance, which assume winners and losers in a contest over resources, people, and power. Yet war is defined differently by the winners and the losers, by historical perspective, by soldiers and pacifists – and in each case the definitions are more politically charged than factually correct. For example, freedom fighter, terrorist, insurgent, rebel, traitor, soldier, deserter, civilian, perpetrator, and victim are all terms variously applied to the same actors by different groups in different contexts seeking to maximize their own political, economical, and moral justifications. Governments define war in their own interests, and militaries are generally loath to admit strategies that entail civilian or noncombatant casualties, torture, and human rights abuses. In using terms such as 'collateral damage,' military powers instead try to trivialize and relativize civilian casualties. As anthropologists often emphasize, the most basic understanding of war is affected by differential and biased reporting; for example, casualty statistics for World War II vary by millions, depending on the nationality and viewpoint of the researcher. Controlling the definitions of war and its consequences is integral to the waging of war (Sluka, 1992).

The ethnographic study of war and peace has added a new dimension in the understanding of political violence. This academic research has demonstrated that war is a far more complex reality than classical definitions positing a violent contest between two or more armed forces seeking a military, and thus political, victory (Warren, 1993; Nordstrom and Robben, 1995). Rather than to settle with any final and universal definition of war, anthropologists have thus come to emphasize the importance of the comparative ethnographic approach with case studies along the war–peace continuum (e.g., Richards, 2005). Soldiers often battle unarmed civilians and not each other – evident from the ethnic cleansing in former Yugoslavia, especially in Bosnia and Kosovo, or the 2 million deaths in the civil war that lead to the independence of South Sudan. Paramilitaries, private militias, death squads, and roving bands of armed predatory gangs patrol war zones. Some operate at the behest of state forces (Sluka, 2000), while others are independent of all sovereign or rebel control, and they may operate in war as well as in peacetimes. Mercenary forces are a global phenomenon today, and range from informal groups such as European mercenaries fighting in Central Africa to the more formal Executive Outcome organization, comprising former apartheid South African soldiers, who broker with governments as well as rebel groups. Battle zones are also home to looters, sex workers, criminals, and profiteers. War zones are a bazaar of international arms and supplies merchants who reap billions of dollars yearly worldwide. International nongovernmental organizations are found in all war zones today, providing services ranging from conflict resolution to humanitarian and development aid (Nordstrom, 2004). Finally, the fronts of wars remain home to the inhabitants. Regardless of formal military regulations mandating the legal role of women, children, and the aged in war, all of these people fight for survival when they find themselves on the frontlines. Armed or unarmed, women defend homes and towns, children are forced to take up arms and fight, and the aged battle forced sieges. The unscrupulous sell out their neighbors for a few coins, and the altruistic set up medical clinics, schools, and trade routes to provide critical resources under bombardment. War, in short, is a social project that sustains the experience of war, making it and its multiple forms of violence routines among other routines in everyday life (Richards, 2005).

The Development of War

War is a fairly recent invention, in terms of the anthropological expanse of human existence. Humans, as a species, have lived 90% of their history without war. Social hierarchies and concepts of ownership appear necessary for the advent of war. The earliest form of human organization was the band: fluid egalitarian groups of nomads. The archeological record indicates that while interpersonal violence was known in bands – determined by puncture and crushing wounds from weapons – it was limited. It did not reach the level of formalized intergroup violence among contending warriors.

The first indications of organized warfare occur as ownership of animals, goods, and property create divisions within societies. With the historical development of tribal societies and protostates comes a differentiation in power, and the emergence of organized intergroup violence (Ferguson and Whitehead, 2000). Such societies did not have standing armies and military institutions separate from general society; warrior status tended to be open to all able-bodied men, and, less commonly, to women. These early years of war were not necessarily a dangerously lethal activity. For many ethnic groups, preparations for war constituted an elaborate ritual process. The rules of engagement were often well delineated: contending factions would meet in full battle regalia and hurl challenges and possibly weapons. Casualties generally brought a halt to the aggressions. Here, it is the display and enactment of power, and not violence, that defines war. Among some communities – the archeological record suggests these were later developments – fighting was much more lethal, though the intent was seldom, if ever, genocide. The goal was to force surrender and extend control over people, property, or territory.

Formalized military institutions and standing armies develop with the rise of the 'state' as a form of political, economic, and social organization. The term state here is used in its broad anthropological sense – originating some 8000 years ago, and not in the political science definition as developing in the mid-1600s. (The latter will be considered in the next section.) So when chiefdoms are replaced by royal families or other, equally centralized governing bodies, standing armies tend to develop as well, while social, gender, and often ethnic inequalities are increasingly codified in laws of land ownership, labor rights, and inheritance. Dispute resolution becomes formalized into judicial systems, and the legitimate use of force is restricted to state leaders and institutions. Contemporary warfare – fought among contenders for power, privilege, gain, and over identity – emerges. Eventually, as we shall see, such developments find fuel from the context of colonial intervention and annexation.

The Changing Nature of War

Contemporary warfare itself has changed dramatically over time and circumstance, giving lie to any notion that war is a 'natural' social phenomenon or a fixed product of overarching political organization (van Creveld, 1991). The era of the modern state provides a good illustration (Holsti, 1996). In Europe, the end of the Thirty Years War (from 1618 to 1648) coincided with the beginning of the modern state (marked by the Treaty of Westphalia). The Thirty Years War depopulated a large part of Central Europe. It was known for its sheer brutality; writers of the time speak of the wanton killing, torture, plunder, and destruction of anyone and anything who found themselves in the path of the aggressors. The levels of violence are attributed to the enduring impact of religious wars and the Inquisition, to the transformations wrought by urbanization and early industrialization, and to the upheavals marking the shift from kingly rule to the modern state.

Over the following two centuries the nihilism characterizing the Thirty Years War gave way to what has been called the gentlemen's war of the Enlightenment period. Formal warfare during this era often, though certainly not always, followed strict rules of conduct and engagement: soldiers fought soldiers

in hand-to-hand combat on battlegrounds apart from human habitation. This was not a new era of war for humankind: Buddhist and Hindu scriptures 2000 years BCE outlined similar 'gentlemen's wars' in Asia.

While military texts tend to focus on these formal military engagements between two contending armies, another form of warfare developed during this period: colonial repression of conquered peoples. It is commonplace to read in amateur ethnographic accounts of the colonial administrators, that war was a constant occupation among non-Western peoples before colonization, but the reader is most often left in ignorance as to what the colonial administrators really meant with the word 'war.' Rather, here the term 'war' was deliberately kept vague so that it could be used in legitimizing imperial and allegedly honorable agendas. The message of these early colonial reports was that colonization brought peace. The reality was far more violent and saw the first genocides of the twentieth century; for example, the annihilation of the Herero people of present-day Namibia. In many ways, these actions presaged the dirty war of contemporary times – wars that brutally targeted unarmed people in attempts to instill political acquiescence.

The colonial encounter eventually gave rise to another distinct form of war: the guerrilla war, the mainstay of wars for independence worldwide. Guerrilla warfare was developed by nonstate actors challenging financially and technologically superior state forces. Classical guerrilla philosophy – institutionalized in the mid-twentieth century by military strategists such as Mao Zedong, Che Guevara, and Ho Chi Minh – postulates that guerrilla forces, by definition, have the support of the broad population, and it is this that gives them indefatigable strength, crucial resources, and moral political superiority. While in many cases this has proven true, it is by no means always so. Guerrilla or insurgency groups such as the Khmer Rouge in Cambodia, Renamo in Mozambique, the Lord's Resistance Army in Uganda, and the Contras in Nicaragua demonstrated that nonstate forces, sometimes even very small, can also use repressive tactics in an effort to control large populations.

In the aftermath of the 11 September 2001 terrorist attacks on the United States, many politicians came to regard the rules and laws of war as obsolete. A fundamental shift in warfare, with truly global repercussions, took place and torture was sanctioned by the democratically elected US government. Then president George W. Bush declared a 'war on terror' and the US-led invasion of Iraq soon developed into a seemingly permanent yet diffuse state of war and insecurity in Iraq as well as in Afghanistan and along the Afghanistan–Pakistan borderlands. The militarization of societies under occupation has deepened, with violent developments that cross-breed in all kinds of global yet diffuse directions. Many observers again reference the idea of a 'military–industrial complex,' formulated by US president Dwight D. Eisenhower as well as, from the other end of the political spectrum, the Trotskyist theory of a 'permanent arms economy,' which was forwarded to explain the sustained economic growth that occurred in the decades following World War II. Back then, as today, wartime capitalism reproduces itself despite the inherently contradictory nature of the capitalist growth cycle (see, e.g., Whitehead and Finnström, 2013).

In the effort to dedramatize the political rhetoric and reclaim the definitional space as well as dislocate global war from the US homeland, the 'war on terror' was eventually renamed 'overseas contingency operations' by the Obama administration. Again it becomes evident, from an anthropological perspective, that the control over the definitions of war is integral to the waging of war.

The Twentieth Century

Overall, wars were longer in duration, more lethal in the cost to human lives, and more destructive to societal systems and the environment in the twentieth century than in preceding times. This era saw the advent of world wars, nuclear war, and modern paramilitary warfare. The most dramatic development of war concerns the ethics of who may and may not be targeted in war. Over 80% of the casualties in World War I were soldiers. But eventually also a country's citizens were to be seen part of that country's war effort, given their role in producing the means of war, or just as potential supporters of a war effort. When this philosophy was married with developments in military technologies such as aerial carpet bombings, the number of noncombatant casualties raises even more (Lindqvist, 2001). Some 50% of all war-related deaths in World War II were noncombatant casualties. This trend escalates in the last half of the twentieth century. The US military intervention in Vietnam resulted in one of the most massive bomb campaigns in history. More than 80% of all casualties in the Vietnam war were noncombatants. At the start of the twenty-first century, civilians account for 90% of all war-related deaths worldwide.

Even if these comparative figures on war casualties can only be estimated in retrospect, and therefore are notoriously uncertain, they certainly indicate that noncombatants rather than only the military enemy are the explicit target in many of today's wars. Not only has the line between combatant and noncombatant grown indistinct, the line between gender and age in soldiering has too. Women die in equal numbers to men, and more children are killed in war today than soldiers. The use of child soldiers has grown in recent years; at the turn of the millennium over 300,000 existed worldwide. If children armed with AK-47s cynically are forced into war because of their effectiveness and loyalty in combat, another truly scary development of global war is the ever-increasing use of deadly high-tech remote-controlled unmanned aerial vehicles or so-called drones.

The serious rise in civilian casualties parallels an increase in the number and sophistication of international organizations (such as the United Nations, the European Union, or the African Union) and international legal bodies (such as the International Criminal Court and the War Crimes Tribunals) seeking to control destructive wars. Today, there are 70 000 protocols protecting human rights. Even if military strategists tend to describe and dehumanize civilian causalities in terms of unintended collateral damage, they also claim the very space of humanitarianism. Military interventions are no longer always clearly distinguishable from humanitarian interventions and vice versa. This, of course, affects global war and how it is perceived on the ground. For example, in the wake of an increasing number of deadly attacks on their personnel, in 2013 Médecins Sans Frontières decided to leave Somalia after more than 20 years there.

Theorizing War

As the predominate means of waging war changes through time, so too do the definitions and theories of war (Simons, 1999). In premodern times, many, including early Christian and Buddhist societies, saw war as inescapable at times, but not as honorable; the postwar period was crafted as one of atonement. The notion of the honorable war develops in the West with the rise of the 'gentleman's war' of the modern state. Carl von Clausewitz, the famous Prussian military expert, codifies war as 'an extension of politics,' placing war directly in the rational politics of Enlightenment philosophy. Warfare, as rational, became justified. As discussed above, the most dangerous examples of this were seen in colonial conquests, often rationalized under the rubric of the 'evolution of civilization' by scholars.

These Enlightenment philosophies wed with the functionalist and structuralist schools in the early 1900s. Here, theoreticians investigated the 'functions' of war, and placed the causes of war in competition over scarce resources, overpopulation, and the increasing complexity of societies. At the same time, psychological and sociobiological theories were popular. They postulated aggression and self-interest as inherent to humans, and therefore as serving an evolutionary purpose.

One contemporary example of such theories on war and human aggression is anthropologist Napoleon Chagnon's work among the Yanomani people in Venezuela (e.g., 1968). With reference to biology, Chagnon argues that Yanomani men are fierce and warlike and that they wage war over women; that Yanomani men who are killers have more wives and children than men who are not; and that war is the prime mover of cultural and human evolution. Chagnon's thesis on warfare stirred one of the biggest and longest debates in anthropology, with the majority of sociocultural anthropologists vigorously questioning Chagnon's conclusions as well as his research ethics. However, in seeing Chagnon's results as evidence of a universal theory on human nature and war, sociobiologists have generally endorsed his work.

The fact that not all societies engage in war, and that the majority of the people in any society at war do not choose to fight was not addressed by the psychological and sociobiological theories. At the same time, twentieth-century political theory was shaped by the advent of World War I and World War II. After World War I, functionalist theories take an idealist cast that postulates the progress of civilization as one that will finally eschew war. In the wake of the vast destruction of World War II, realist theory replaces idealism as the dominant theory in the social and political sciences. Here, war is seen as a natural effect of competition among sovereign states. In both schools the solution lies in creating strong state and international institutions to wage, and ideally to control, war.

As the period of the World War I and World War II gave way to wars for independence, regional wars, and the Cold War, theories of war underwent another revolution. Critical to this shift is the fact that researchers around the world began to experience political violence directly, whether by intention or by accident. The reigning functionalist theories did not fit their observations (Foster and Rubinstein, 1986). Consequently, by the 1990s the anthropological focus had shifted from such theories on the causes, structures, and functions of war to the study of lived experiences of war, especially coping mechanisms among allegedly innocent victims caught in cross fire. Eventually, anthropologists saw the importance to account also for the stories of perpetrators as well as the larger sociopolitical structures (Löfving, 2005). Today, most anthropologists again emphasize both cause and effect, both (objective) structure and (subjective) agency. War structures the lived experiences, motifs, strategies, and tactics of all kinds of agents of war – victims, perpetrators, profiteers, or bystanders – but as these social agents 'navigate terrains of war' (Vigh, 2006), they also structure war.

The advent of nuclear war gave lie to ideals of 'victory' in war – for the first time all sides to a conflict could perish. Wars such as those fought by the United States in Vietnam and by the Union of Soviet Socialist Republics in Afghanistan, the more recent global terrorism of al-Qaeda and other groups, and subsequently, the war on terror laid to rest old notions of the gentleman's war. Dirty wars such as those in Argentina, and genocides such as those conducted by the Nazis in World War II and by Hutu extremists in Rwanda, as well as the Khmer Rough's immeasurable mass killings in Cambodia challenged notions of the inherent functionality or rationality of war. The increases in noncombatant deaths undermined the claims of sociobiology – it became hard to argue that noncombatant deaths, widespread torture, systematic sexual violence, and the death of children were biologically or socially productive acts (Enloe, 2000). Scholars also began to question Clausewitz's 'truism' that war is (predominately) an extension of politics. Certainly it is political, but the recognition of the vast sums of money made in wildcatting valuable resources in war zones and in selling war supplies worldwide made it necessary to integrate economics with politics in the war equation (Kaldor, 1999). The rise of religious, ethnic, and identity dynamics in contemporary conflicts rendered it necessary to account for social and cultural factors in any politicoeconomic analysis (Rupesinghe and Rubio Correa, 1994). And studies of peaceful societies such as the Semai and the Quakers demonstrated that war is not inevitable, nor basic, to the human condition (Gregor, 1996).

In holistically acknowledging the above-mentioned factors, anthropological theorizing on war and culture tend to emphasize two propositions. First, war and culture cannot be studied as things in themselves, and war is only one among many competing social projects along the war–peace continuum. Second, and following the first proposition, in refuting reductionist explanations of any essence of war (or culture), anthropologists promote globally framed indepth and historicized ethnographic case studies of both war and peace. Today, these are carried out in specific locations as well as in transnational and virtual spaces, and sometimes, if needed, even from a distance (Richards, 2005; Robben, 2010; Whitehead and Finnström, 2013).

The Future of War

The dawn of the third millennium is marked by vast differences in war. While the superpowers spend trillions of dollars on high-technology earth- and space-based weapon systems as well as on the software of anthropological intelligence in the form of the highly contested Human Terrain System (Gonzalez,

2009; Price, 2011; Whitehead and Finnström, 2013), the vast majority of today's war casualties are killed by small arms wielded by nonspecialists. The greatest dangers are the most accessible; there are estimated to be 500 million to 1 billion firearms in use today in the world; a lively international black market sells every conceivable implement of war from AK47s to nuclear materials; recipes for chemical weapons and homemade bombs can be found in basic texts; and computer specialists can potentially hack a drone aircraft or wreck nationwide havoc by disrupting a country's basic infrastructural support systems. There is a growing trend among governments to regard and declare cyber-attacks on their state infrastructures as acts of war, as well as for governments themselves to initiate cyber-attacks on infrastructures of proclaimed and nonproclaimed enemies.

All facets of the war industry are set in global interactions (Castells, 1998). Our theories of war must be revised to address these dynamics defining the contemporary world. Theories of war need to address the complexities of war systems that spend fortunes on technological defenses (at the end of the twentieth century military spending worldwide reached 780 billion US dollars per year) while killing with inexpensive conventional weapons – and will delve into the sociocultural factors and economic gains as well as the political quests that underlie these realities. It can also be contended that the killings on the actual battlefields, wherever they are located, are intimately linked to an emerging virtual space created by news and gaming media as well as the technologies of contemporary military violence – such as airborne attack drones, satellite surveillance, stealth airplanes, and the associated use of politically covert assassination operations. This is the character of war today, which has definitively moved beyond the confines of nation-states and through mechanisms such as 'peacekeeping,' terrorist interdiction, 'target killings,' and 'overseas contingency operations,' and now has a global and increasingly permanent character (Whitehead and Finnström, 2013). Consequently, in recent times the anthropological study of war affirms to a renewed interest in the state, state sovereignty, and related questions (e.g., Kapferer and Bertelsen, 2009).

While employing violence in the pursuit of dominance may continue to fuel war, violence may shift from physical killing to a different order of threat and inequality, and dominance might be reckoned along such nonmilitary factors as economics, environmental control and climate change, social viability, or a set of factors as yet unrecognized. In the long term, we should be prepared for the possibility that war, as we used to know it, may not define future conflict. War has not always been a part of the human condition, and perhaps future changes in sociopolitical organization and ethical systems will render war altogether obsolete. Effective research into the lived experiences, causes, and future of war and peace will hone combinations of theoretical inquiry with ethnography – helping to erase arbitrary distinctions between theory and data (Nordstrom, 1997). The greatest advances will be in rethinking the very meanings of war and aggression, going beyond simple biological and rudimentary social explanations to explore the complex interactions of violence and power, capital and resources, economics, survival, and identity both within and across local, regional, and transnational populations.

Abstract

Ideas related to war crimes tribunals, crimes against humanity and transitional justice have evolved considerably since the codification of international humanitarian law in the nineteenth century. After the Second World War, a number of new crimes, including genocide, crimes against humanity and war crimes, were codified and adjudicated in international tribunals in Nuremburg and Tokyo. International war crimes tribunals reemerged in the 1990s to deal with the violence that occurred in the break-up of the former Yugoslavia and in Rwanda. Currently, there exist an international treaty-based tribunal, two subsidiary bodies of the United Nations, hybrid tribunals that blend domestic and international law, and domestic tribunals that try international crimes. These tribunals are an important component of transitional justice, an idea that has emerged over the past two decades and offers theoretical and practical tools to the challenges that governments face in their efforts to redress past and ongoing violence.

Contemporary Origins

War crimes and crimes against humanity emerged as a category of international law in the latter half of the nineteenth century, when international humanitarian law, or the body of laws regulating war, was first delineated in international treaties. Prior to this time, those who committed wanton acts of violence during war were treated as traitors, usurpers or enemies (Bass, 2001). The International Committee of the Red Cross (ICRC) played a major role in convening world powers to sign the Geneva Convention of 1864, which regulated the protection of the sick and wounded during war. Although debates that led to the Geneva Conventions and other treaties at the time included topics related to crimes related to *jus ad bellum* (the right to go to war), the Conventions focus on *jus in bello* (legal provisions pertaining to conduct during war) (Sloane, 2009). Several other treaties followed the initial Geneva Conventions of 1864, including the Brussels Declaration of 1874, the Geneva Convention of 1906, and the Hague Conventions of 1899 and 1907. In 1929, after the First World War (WWI), world powers convened and passed another round of the Geneva Conventions, which specified the treatment of prisoners of war and the treatment of the sick and wounded. In 1949, after the Second World War (WWII), state representatives updated the three prior Geneva Conventions and added a fourth. In 1977, they passed Protocols I and II, which specify the treatment of victims of both international and non-international armed conflict.

War crimes are generally considered 'grave breaches' of the Geneva Conventions and Protocol I, which governs international armed conflicts. Legal decisions in war crimes tribunals, discussed below, have extended the definition of 'grave breaches' to include internal armed conflicts, which are governed by Common Article 3, an article found in all four Geneva Conventions, as well as by Protocol II. The ICRC describes grave breaches as including willful killing, torture or inhumane treatment (including biological experiments), willfully causing great suffering or serious injury to body or health, and willfully depriving a protected person of the right to a fair trial if accused of a war crime. The Fourth Geneva Convention also restricts the taking of hostages, unnecessary and extensive destruction of property, and unlawful deportation, transfer or confinement (Henckaerts et al., 2005). The idea of crimes against humanity was articulated in 1915 by Woodrow Wilson in reaction to the Armenian genocide, though the idea that certain actions that violate all humanity existed long before (Bassiouni, 2011).

A number of other treaties clarify regulations around the means and methods of warfare, while declarations and other nonbinding statements form the basis of customary law or customs of war. These various sources comprise the legal foundation of war crimes tribunals and influence current understandings and practices related to transitional justice.

The First and Second World Wars

The first issue addressed at the Paris Peace Conference, which ended WWI, was the punishment of war criminals (Bass, 2001). After WWI, Britain and France attempted to try Kaiser Wilhelm I for the violence that ensued after Germany invaded Belgium and Luxembourg. Article 227 of the Treaty of Versailles contained a clause stating that the Allied powers would arraign the Kaiser "for a supreme offense against international morality and the sanctity of treaties," while Article 228 asked for Germans who had "committed acts in violation of the law and customs of war" to be extradited to London. Neither the Netherlands, which was hosting the Kaiser, nor Germany, where the other defendants resided, participated willingly in the process. The compromise – to hold the trials in Germany's Supreme Court – led to lenient sentences and several acquittals. The Kaiser was not extradited and ultimately died in the Netherlands after the start of WWII. While victims of German aggression felt the trials were too lenient, many Germans felt that they were too harsh. Some argue that these provisions for trials fanned the flames of resentment in Germany, fomenting the aggression that led to WWII.

With the international institutions that were created in the wake of WWII, the modern era of international criminal law began. After Germany's defeat, the allied powers came together to design a process to punish Germany for the horrific violence

it perpetrated. The United Nations War Crimes Commission was established in 1942 and began collecting names of individuals suspected of war crimes (Davidson, 1966). The US had warned Germans about charges for war crimes even before it joined the War. After the war ended in 1945, the allied powers drafted the London Agreement. One of the major concerns had to do with whether the defendants could be charged with waging war. France and Russia were especially concerned about this, but the Americans were influential in their position that Germany could and should be tried for crimes against the peace (Bass, 2001). After negotiations about whether all Nazis, or just their leaders, should be tried (or, as some American government officials expressed, should be hanged), 24 men and six organizations were put on trial at Nuremburg.

The International Military Tribunal (IMT) at Nuremburg has become a model of the international war crimes tribunal (Meron, 1994). It was a treaty-based tribunal, outside the mandate of the newly formed United Nations. It tried the 22 senior Nazi officers for war crimes and crimes against humanity. War crimes were defined as "violations of the laws and customs of war," particularly "murder, ill-treatment of deportation to slave labor," "murder or ill-treatment of prisoners of war," as well as "destruction of cities, towns, or villages, or devastation not justified by military necessity," while crimes against humanity were defined as "murder, extermination, enslavement, deportation and other inhumane acts committed against any civilian population, before or during the war," or "persecutions on political, racial or religious grounds in execution of, or in connection with," war crimes and crimes against the peace, regardless of whether they were legal or illegal under domestic law (London Charter, 1945). The tribunal also applied the doctrine of conspiracy, known primarily in the common law system, to heighten charges, but the judges only allowed for a conspiracy charge to be added to the crime of aggression charge (Bass, 2001).

The trials themselves were a remarkable undertaking, yet procedurally deficient in a number of respects (Davidson, 1966). Thirteen trials were held; all but one were presided over by American judges. Americans represented half of the total workforce in the Tribunal (there were over 600). The defense had no access to the documents held by the prosecution. German lawyers had to specify what they wanted, and they only had a month to prepare their pleas. Twelve of the accused were sentenced to death, 10 were eventually hanged (one died committing suicide the night before his scheduled execution and the other, who was tried *in absentia*, died while trying to escape Germany at the end of the war), seven received prison sentences for periods ranging from 10 to 20 years, and three were acquitted.

Later trials were held for lower ranking officers (Zeck, 1947). Trials known as the Subsequent Nuremberg Proceedings involved another 12 high-ranking officers, and the United States Nuremberg Military Tribunals held trials of 177 additional individuals. Under Allied Control Council Law No. 10, German tribunals were also created to try those accused of war crimes. Over 900 defendants were put on trial in these domestic courts, although there are a number of critiques about the lenient sentences and procedural deficiencies in these domestic tribunals (Ferencz, 1998).

The Nuremburg trials led to a number of important innovations in legal doctrine regarding war crimes. In particular, the Charter explicitly stated that individuals could be held liable for actions they were commanded to undertake, paving the way for both subordinates and state leaders to be held individually liable for actions committed during conflict. Although the crime of conspiracy was only allowed as an additional charge in relation to crimes against the peace (now known as the crime of aggression), the jurisprudence on conspiracy provided a foundation for contemporary doctrines of vicarious liability.

While Nuremburg is often seen as victor's justice, it is usually celebrated as a progressive example of international justice. In contrast, the International Military Tribunal for the Far East (IMTFE), commonly known as the Tokyo Tribunal, is often viewed as the example of postwar justice gone wrong (Danner, 2005). Its establishment was not the product of allied negotiations but rather resulted from the unilateral efforts of US General Douglas MacArthur. The tribunal focused on individuals accused of crimes against the peace, but it also allowed for additional charges related to war crimes and crimes against humanity. Whereas Nuremburg did not adjudicate crimes perpetrated before the start of the war, the IMTFE investigated actions all the way back to 1931, and the judges were much more liberal with conspiracy charges (Boister, 2010) The prosecutor was from the United States, and the 11 judges included representatives from the nine nations involved in the Japanese Instrument of Surrender, as well as India and the Philippines.

The defendants included 28 members of the Japanese military and political establishment, but the Emperor was granted immunity. The trial lasted over 2 years and 3 months, and it included 419 witnesses. The tribunal faced a number of dilemmas related to linguistic and cultural differences between the participants, as well as procedural irregularities (Maga, 2001). The judgments included five separate opinions and two dissenting opinions that highlighted the level of internal discontent with the proceedings. The sentences, decided by a simple majority, led to death by hanging of seven defendants. Interestingly, those who survived the sentencing were all released unconditionally by 1958, after American occupation ended in 1952 and domestic pressure mounted to release not only these defendants, but also the thousands of lesser ranked military personnel prosecuted by foreign nations.

International Criminal Tribunal for Rwanda and International Criminal Tribunal for the Former Yugoslavia

Although there was momentum in the post war years to create a permanent tribunal to deal with international crimes, the Cold War stymied efforts to collaborate on such an endeavor. The next two international war crimes tribunals were designed to be temporary, inspired by failure to stop the devastating violence that ensued in the break up of the former Yugoslavia and the genocide in Rwanda. These tribunals ushered in a new era of international criminal law as the United Nations drew on Chapter VII of its Charter, which enables it to intervene in domestic affairs of member nations in order to maintain international peace and security. Pursuant to this authority, the

UN created two subsidiary bodies to try those most responsible for the devastating violence in these regions.

On 25 May 1993, the UN Security Council established the International Criminal Tribunal for the Former Yugoslavia (ICTY), "for the prosecution of persons responsible for serious violations of international humanitarian law committed in the territory of the former Yugoslavia" (UN Resolution 827). UN Security Council Resolution 827 defined the Tribunal's substantive jurisdiction over 'grave breaches' of the Geneva Conventions, violations of the laws or customs of war, genocide, and crimes against humanity. Notably, unlike the Nuremberg Tribunal, the ICTY had no authority to prosecute states for aggression or crimes against peace. Its mandate specified that the Tribunal was expected 'to put an end to such crimes' and, by bringing those responsible to justice, to 'contribute to the restoration and maintenance of peace' (ICTY Statute).

After the massacre at Srebrenica, later declared by the International Court of Justice to be an act of genocide, the international community intervened to stop the bloodshed and broke the Dayton Peace Accords in 1995. Two years later, the ICTY conducted its first trial of a mid ranking Serb officer. Given the nature of the violence and the leadership structure within the armed forces, the ICTY statute adopted an expansive understanding of individual criminal responsibility to include two types of vicarious liability, meaning liability for crimes that the accused did not personally commit (Danner and Martinez, 2005). Under the theory of command responsibility, a superior officer is individually criminally responsible for the acts of his subordinates when he knew or should have known that his subordinates were going to commit a war crime and failed to prevent such an occurrence. Moreover, a superior officer who learns that a subordinate has committed a war crime and fails to punish the actor is likewise criminally responsible for the offense. The doctrine of liability known as joint criminal enterprise (JCE) enables liability for the "participation in the realization of a common design or purpose." This theory of liability was the foundation of many convictions at the ICTY, and remains a controversial doctrine for its expansive notion of individual responsibility.

The ICTY also tried those accused of crimes committed in Kosovo in 1999. Slobodan Milosevic, widely considered responsible for igniting the violence that ensued in the break up of the former Yugoslavia, was ultimately indicted for his role in the violence in Kosovo, but he died before the conclusion of his trial (Hagan, 2003).

While remarkable for its contributions to international criminal law, there are a number of critiques of the ICTY. Many suggest that the tribunal was too expensive, costing US$2.2 billion over 20 years. Moreover, among the thousands responsible for committing atrocities, only161 individuals have been indicted and only 141 cases have been completed. There have been 18 acquittals, and 36 indictments withdrawn, including six defendants who died before their trials concluded (ICTY Facts and Figures). Although atrocities occurred to all ethnic groups and in all countries, a vast majority occurred in Bosnia and Herzegovina, where Bosnian Serbs waged a campaign of violence against Bosnian Muslims. Various studies point out that opinions of the tribunal reflect the ethnic divides in the region, with Serbs feeling unfairly targeted by the tribunal and Bosnian Muslims feeling that plea bargaining, reduced sentences and acquittals have revictimized them (Delpla, 2007). Given the Tribunal's location in The Hague, there are ongoing questions about its impact on the restoration and maintenance of peace (Nettelfield, 2010).

The International Criminal Tribunal for Rwanda (ICTR) is similar to the ICTY in a number of ways, and it has faced similar challenges related to its procedural and substantive limitations (Møse, 2005). The tribunal had a narrow mandate to "prosecute persons responsible for serious violations of international humanitarian law committed in the territory of Rwanda … between 1 January 1994 and 31 December 1994" (UN Resolution 1503). The Tribunal was established to address the extremist Hutu-led slaying of approximately 800 000 ethnic Tutsis and thousands of politically moderate Hutus. After the violence, the Tutsi-led Rwanda Patriotic Front (RPF) became the ruling political party and asked the United Nations to create the tribunal. Later, the government expressed concern about a number of key provisions, particularly the ICTR's proposed structure, jurisdiction, and location in Arusha, Tanzania, which is far from the site of the violence and thus far from public view (Waldorf, 2006). Rwanda ultimately voted against the resolution that created the tribunal.

In its November 2013 report, the Tribunal declared that it had concluded the substantive work in the trials against 93 individuals. There were 55 first-instance judgments involving 75 accused, 10 referrals to national jurisdictions, three cases that were transferred to the International Residual Mechanism for Criminal Tribunals, two withdrawn indictments, and three defendants who died prior to or in the course of trial. All of the appeals are expected to be concluded by 2015 (ICTR, 2013).

A noticeable difference between the ICTR and the ICTY relates to their respective definitions of international crimes, particularly crimes against humanity (Cryer, 2005). The Rwanda conflict was noninternational in character, so Common Article 3 of the 1949 Geneva Conventions, as well as Protocol II, were applicable. The provisions on genocide in both statutes are the same as the Genocide Convention. Unlike the ICTY statute, the Rwanda Statute does not require that crimes against humanity be connected to armed conflict. Moreover, the ICTR Statute expressly requires that the enumerated inhumane acts be committed against a civilian population "on national, political, ethnic, racial or religious grounds." Unlike other tribunals, which apply the idea of a "serious breach of the Geneva Conventions" to armed conflict, the ICTR statute applied 'serious breach' to Common Article 3 of Geneva Conventions, which applies to noninternational armed conflicts. It also expanded the jurisprudence so that civilians can be held liable for war crimes, and it tied the notion of crimes against humanity to noninternational conflicts (Kamatali, 2005).

The Tribunal is perhaps most notable for its jurisprudence on genocide and sexual violence. It became the first international tribunal to find a defendant guilty of genocide; it also concluded that rape can constitute a crime against humanity and an act of genocide. Moreover, it delineated the difference between sexual assault and rape, concluding that rape need not include intercourse (Amann, 1999). The tribunal also held that media leaders could be held individually accountable if they publish propaganda that incites genocide (Gordon, 2004).

Though generally less controversial than the ICTY, ICTR has been strongly criticized for its inability to adequately address

the causes and the consequences of the genocide (Kamatali, 2005). First, it did not try the Rwandan Patriotic Front (RPF), the current ruling political party, for the group's alleged atrocities. Second, there are a number of concerns about the tribunal's limited temporal mandate to only try crimes committed in 1994. This limited time frame obfuscates the conflict's origins and its ongoing effects in the region, particularly Rwanda's role in the violence that continues to destabilize the Democratic Republic of Congo. Moreover, the trials have been held far away from Rwanda, and thus had a limited impact on how Rwandese population viewed the violence.

The International Residual Mechanism for Criminal Tribunals, or the Residual Mechanism, is the judicial body authorized to take over cases from the ICTY and the ICTR. The Mechanism began its work for ICTR cases in 2012 and for ICTY cases in 2013. This mechanism is supposed to try senior leaders responsible for the violence, handle appeals and charges of contempt, and retrials. But it has a host of other responsibilities too: it is supposed to help enforce sentences, assist national authorities in trying accused parties who are not senior leaders, help with the protection of witnesses in completed cases, aid the ongoing efforts to apprehend fugitives, and manage the Tribunal archives (United Nations Mechanism).

Hybrid Tribunals

By the early 2000s, the ad hoc tribunals were costing the UN nearly 10% of its overall budget, and efforts to domesticate international criminal law came to the fore (Dougherty, 2004). In addition to the ad hoc tribunals, the United Nations has created two hybrid tribunals, the Special Court for Sierra Leone (SCSL) and the Special Tribunal for Lebanon (STL), that blend international and domestic criminal law. While the STL covers transnational terrorism and not war crimes, the creation and operation of the SCSL represents a unique effort to domesticate international war crimes tribunals through the blending of domestic and international practices.

The war in Sierra Leone began in 1991 when the Revolutionary United Front (RUF), supported by Charles Taylor in neighboring Liberia, attempted to overthrow the ineffectual and corrupt government. By the time the conflict officially ended in 2002, an estimated 60 000 people had been killed, nearly 2 million displaced, and 20 000 abducted; nearly 7000 child soldiers had been disarmed. Like Rwanda, the government of Sierra Leone wrote to the UN Secretary General requesting the international body to try rebel leaders for crimes against the people of Sierra Leone and for taking United Nations peacekeepers as hostages (Fritz and Smith, 2001). For 2 years before the conflict officially ended, the UN worked with the government of Sierra Leone to create a tribunal in order to address allegations of horrific acts of violence. The Court had jurisdiction over crimes against humanity, war crimes, defined as violations of Common Article 3 of the Geneva Conventions and Additional Protocol II, which pertain to internal armed conflict, as well as other serious violations of international humanitarian law.

The SCSL is distinct from the ad hoc tribunals in a number of important ways (Dougherty, 2004). The Tribunal incorporated Sierra Leonean laws that prohibit sexual violence against girls and the wanton destruction of property, specifically arson, because the rebels frequently burned buildings. It was located in Sierra Leone, where the violence took place, which addressed concerns that the ad hoc tribunals were too far from the victims. However, unlike the ad hoc tribunals, the SCSL required voluntary donations. Even after the Secretary General halved his initial request for a 3-year operation budget, there was a US$21 million shortfall from the original requests. With first year contributions amounting to a little over 10% of the ICTY's annual budget, the SCSL was severely limited in its operations; it had to rely on donations for the third year in order to continue operating through the second year.

The tribunal has been criticized for its procedural and substantive limitations, particularly the lack of due process afforded the defense through equality of arms and evidentiary standards (Combs, 2010). The tribunal also did not have United Nations Chapter VII powers, meaning that it could not compel state authorities to hand over indicted individuals (Fritz and Smith, 2001). When the SCSL indicted Liberian President Charles Taylor, it struggled to get cooperation from Ghana, where Taylor was attending peace talks to end Liberia's Civil War. Taylor went into exile in Nigeria but was eventually handed over to The Hague in 2006. Although he boycotted the trial, he was eventually found guilty on all counts and sentenced to 50 years in prison.

There are other ongoing efforts to try war crimes and crimes against humanity at a domestic level. Among these efforts, the War Crimes Chamber of Bosnia-Herzegovina is notable for being an early attempt to domesticate international criminal law (Garbett, 2010). In July 2002, the Security Council put forth a strategy to encourage domestic jurisdictions to try lower level perpetrators; it secured €15.7 million for the endeavor. Following these developments, the War Crimes Chamber in Bosnia and Herzegovina was created in 2005. The Chamber is part of the State Court of Bosnia-Herzegovina's Criminal Division. It hears cases referred by the ICTY, but can also bring its own cases under domestic law. In July 2013, the European Court of Human Rights found that two defendants experienced a violation of Article 7 of the European Convention on Human Rights, which prohibits 'punishment without law,' because the Chamber retroactively applied its 2003 Criminal Code for violations that occurred in 1992–93. The Court specifically noted that, because the men were found guilty of war crimes (not only of crimes against humanity), and because they were not found criminally liable for any loss of life, they were entitled to greater procedural and substantive safeguards than the Chamber had provided (Zuvela, 2013).

There have been several other recent attempts to use domestic courts to try leaders accused of international crimes (Roht-Arriaza, 2013). In particular, Guatemala's penal code from 1973 includes a provision on genocide and 'crimes against obligations to humanity,' which refer to the country's obligations under the 1949 Geneva Conventions and were used to indict the country's former president, Efrain Rios Montt, and his defense minister. In May 2013, Montt was found guilty of genocide and war crimes for his leadership during the military campaign that decimated the Ixil Mayan population during an internal armed conflict against Communist rebel groups. The trial was controversial within Guatemalan society; many of the ruling elite supported Montt,

and the current president was implicated in the violence. The Constitutional Court annulled the sentence 10 days after it was handed down, ordered that the trial restart, and later held that, due to a technicality about when her 4-year term officially began, the Attorney General who pursued the case must step down 7 months before her formal appointment ends.

In another problematic example of domestic trials for international crimes, opposition leaders in Bangladesh came to power on a platform that included the prosecution of alleged war crimes during the violence that ensued in the 1971 partition (Luban, 2013). Several of the accused were high-ranking officials in the previous ruling party. The tribunal relied on the 1973 International Crimes Act, which allowed for domestic prosecutions of genocide, crimes against humanity and war crimes. The Tribunal has been heavily criticized for its lack of procedural safeguards, as well as harsh sentences, including the death penalty, in a highly politicized atmosphere.

International Criminal Court

In 1948, the UN General Assembly adopted the Convention on the Prevention and Punishment of the Crime of Genocide, calling for criminals to be tried "by such international penal tribunals as may have jurisdiction." The UN invited the International Law Commission (ILC) "to study the desirability and possibility of establishing an international judicial organ for the trials of persons charged with genocide." In 1950, the ILC, comprising 34 individuals chosen 'as persons of recognized competence in international law' from 'the principal legal systems of the world,' was tasked with creating a draft code of offenses against the peace and security of mankind (Clarke, 2009).

However, after the ILC drafted its statute in 1951, it was difficult to bridge the divides that arose during the Cold War (Schiff, 2008). While formal efforts to create a permanent international criminal tribunal were stalled, the idea lingered. In the 1970s, advocacy groups in the United States and elsewhere began to increase their activities in international affairs. In 1981, the General Assembly asked the ILC to restart its work on a draft code of international crimes, culminating in the Convention Against Torture in 1985. In the late 1980s, the chance to create an international tribunal reemerged. The Prime Minister of Trinidad and Tobago, also the director of a non-governmental organization (NGO) called the Foundation for the Establishment of the International Criminal Court, began to lobby for international coordination to combat drug trafficking. In June 1989, the Minister proposed "the establishment of an international criminal court with jurisdiction to prosecute and punish individuals and entities who engage in, inter alia, the illicit trafficking in narcotic drugs across national borders."

One of the main concerns about a permanent tribunal had to do with the international crimes over which it would have jurisdiction, as well as its relationship with existing international institutions (Roach, 2006). When representatives from the United Nations investigated alleged war crimes in Yugoslavia, they recognized the need for a permanent tribunal to focus on genocide, crimes against humanity and war crimes. In 1993, the International Law Commission offered a draft statute for the ICC. The General Assembly sent it back to the ILC for more discussions, including how to define crimes against humanity in light of the variety of definitions in earlier tribunals (Bassiouni, 2011). Over the next 5 years, coalitions of advocacy groups lobbied heavily for the creation of a permanent tribunal. On 17 July 1998, representatives from a majority of states signed the Rome Statute, the treaty that lays out the ICC's rules and procedures.

The ICC has subject matter jurisdiction over what are now known as the core crimes of international criminal law: war crimes, crimes against humanity, genocide, and the crime of aggression. The statute defines war crimes as 'grave breaches' of the Geneva Conventions, and 'serious violations' of the laws and customs of international armed conflict. It also offers a more limited list of offenses for armed conflicts not of an international nature. It drew on the ICTR definition of crimes against humanity; the acts need not be linked to an international armed conflict, but the actions must be part of state policy in order to qualify (Bassiouni, 2011). Interestingly, the crime of aggression is not enforceable until at least 2017, and not until 30 states ratify amendments that clarify the crime's definition as well as the procedure for referring it to the Court (Trahan, 2011). These amendments include a provision that enables signatories to the Rome Statute to opt out of jurisdiction for acts of aggression.

The United States, along with China, Iraq, Israel, Libya, Qatar and Yemen, voted against the Rome Statute. The US later signed on, but then, under the Bush administration, 'unsigned.' The US government's concerns are related to the crime of aggression, as well as the prosecutor's perceived independence and ability to make decisions that could run counter to US interests (Scheffer, 1999). The ICC prosecutor has the ability to open up cases against countries at her or his discretion so long as the alleged crime was committed on the territory of a state that has ratified the Rome Statute (also known as a State Party), or by a national of a State Party, though he or she cannot bring a case against someone in the custody of a State Party. If the alleged crime does not fall into these categories, an ICC investigation may be commenced by the Security Council, pursuant to Chapter VII of the UN Charter.

There are other jurisdictional hurdles, though. For example, the Court follows the principle of complementarity, meaning that it can only act if a state with jurisdiction is not able or willing to carry out its own proceedings (Clarke, 2009). Moreover, if the Prosecutor initiates an investigation, he or she must ask the Pre-Trial Chamber to approve the investigation. Following approval, victims must be informed and invited to contribute to the investigation. Lastly, the ICC must notify the state with jurisdiction over the alleged crimes, and the state can request a deferral. Investigations or prosecutions may be deferred for a period of 1 year, renewable, at the Security Council's discretion.

A striking innovation by the ICC has to do with its treatment of victims, a group that other tribunals overlooked (Stahn et al., 2006; Stover, 2007). For instance, the Victims' Participation and Reparations Section helps victims to apply for participation in proceedings or reparations, and it provides legal advice where needed. Two other agencies also provide support to victims – The Victims and Witnesses Unit and the Office of Public Counsel for Victims. The Trust Fund for Victims, established separately from the ICC, requires separate contributions but does similar work as the various parts of the ICC.

Soon after the ICC came into existence, the Congo and Uganda referred cases to the Court in order to address their internal armed conflicts. The first trial, in which Congolese rebel leader Lubanga was charged with the recruitment of child soldiers, ended in an unconditional release by the Trial Chamber. Although this judgment was later overturned by the Appeals Chamber and Lubanga was ultimately convicted and sentenced to 14 years in prison, the proceedings highlighted a number of concerns about the Court's capacity to fulfill its mandate. Among other dilemmas facing the prosecution, the first witness who took the stand had previously claimed to be a child soldier under Lubanga's command, but recanted this claim in court (Sarvarian, 2013).

The ICC continues to face criticism for the politically sensitive decisions it must make. The first prosecutor of the ICC made a number of controversial decisions, such as indicting the sitting president of Sudan for genocide in Darfur and not pursuing an investigation in Gaza. All of the 21 cases thus far have focused on defendants from Africa, but to be fair, four of these cases were referred by State parties and three were referred by the Security Council. Furthermore, the Court has recently been pursing investigations in other countries, notably in Colombia and Cambodia.

Transitional Justice

Transitional justice was originally conceived as a way to describe how 'emerging democracies' reckon with former regimes, with a focus on the various kinds of justice that countries may seek (Kritz, 1995; Teitel, 2000). The idea captures both (1) a jurisprudential theory about justice in times of political transition and (2) an associated set of approaches/tools/mechanisms to help ensure accountability, improve survivor well being, and prevent future violence (Gray, 2005). War crimes tribunals are considered one of the many mechanisms of transitional justice; the others include truth commissions, reparations programs, memorials, lustration and democratic institutional reforms.

Though originally discussed in relation to countries undergoing regime change, the idea of transitional justice is now applied to settler regimes, countries in ongoing conflict, and countries with no clear democratic transition (LaPlante and Theidon, 2006; Winter, 2013). Some consider transitional justice as a field, others refer to transitional justice as a discipline within the well-established field of human rights, the difference being that transitional justice focuses on political expediency while human rights focuses on legal accountability (Arthur, 2009; Bell, 2009). Early critics suggest that there is nothing out of the 'ordinary' about transitional justice, arguing that law is never devoid of politics and always reflects trade-offs of expediency (Posner and Vermeule, 2004). However, the idea is now taken for granted when discussing how to ensure justice for past, as well as ongoing, atrocities.

In particular, transitional justice was articulated in relation to concerns that holding trials for former leaders would destabilize newly formed governments (Brito et al., 2001). For example, after experimenting with trials, some of which were criticized for their lenient sentences, Argentina and Chile passed various laws that ensured amnesty for military leaders. The countries also created highly publicized truth commissions. While arguably necessary to ensure political stability at the time, various amnesty laws have been challenged, and even overturned, in recent years and military personnel have been put on trial (McEvoy and Mallinder, 2012).

At the close of the twentieth century, with international attention focused on the end of apartheid and the South Africa Truth and Reconciliation Commission (TRC), the idea of transitional justice became increasingly prominent in scholarly, advocacy, and policy making circles (Teitel, 2003). For years, the various parties debated the trade-offs between achieving truth, or an accurate historical record, and justice, usually referring to legal accountability, in countries undergoing regime change (Zalaquett, 1994). Part of these debates has to do with misconceptions about the South Africa experiences. The TRC did not offer blanket amnesty in exchange for confessions. Rather, the Commission consisted of three panels, one that was responsible for approving amnesty applications based on strict criteria about the political nature of the perpetrator's actions, another that held public events and produced a report on the violence, and another that made recommendations for reparations. While lauded for its contribution to maintaining political stability in South Africa, the Commission has been heavily critiqued for misrepresenting the structural nature of the violence and for the fact that the government has not yet provided full reparations (Mamdani, 2002; Wilson, 2001).

These earlier debates about truth versus justice have largely subsided as a consensus has emerged that both goals are part of the holistic conception of justice that is necessary to redress violence and prevent its recurrence (Roht-Arriaza and Mariezcurrena, 2006). The scholarly literature on transitional justice increasingly focuses on the efficacy of war crimes tribunals, truth commissions, and other approaches (Olsen et al., 2010). In addition, scholars, policy makers, and advocates are paying increased attention to local practices in order to inform their efforts to ensure justice (Shaw et al., 2010). From the community truth-telling panels in East Timor to the cleansing rituals in Uganda, local justice practices are being incorporated into recommendations for redressing international crimes (Roht-Arriaza and Mariezcurrena, 2006).

Of course, these local justice approaches are not without critique; just as there are questions as to whether approaches from one country can be transplanted to another, there remain a number of concerns about whether or to what extent local practices, which are designed for smaller scale disputes, can readily be applied to the kinds of violence that trigger the jurisdiction of international criminal law (Hinton, 2010). The idea of 'local justice' in these cases may actually undermine due process by not providing procedural safeguards for defendants and encouraging potentially false witness statements (Waldorf, 2006). Scholars, policy makers and advocates continue to search for optimal combinations of formal justice mechanisms, like tribunals, and community-based practices that can ensure justice for mass violence and prevent its recurrence.

War, Political Violence, and Effects on Children

Christine E Merrilees, State University of New York, Geneseo, NY, USA

This article is a revision of the previous edition article by E. Cairns, volume 24, pp. 16360–16363, © 2001, Elsevier Ltd.

Abstract

The changing nature of war and political violence has increased the likelihood that children will be impacted either directly or indirectly by armed conflict. The study of children in contexts of war and political violence is transdisciplinary, with our knowledge about the effects of these events coming out of psychology, sociology, political science, public health, and anthropology, among other disciplines. Exposure to war and political violence is related to a range of responses including negative, neutral, and even positive adaptation. This article will overview the current knowledge regarding the complexity of children's responses to war and political violence.

Overview

The effects of war and political violence on children are complex and require transdisciplinary study of the multiple overlapping factors that play roles in development of children and adolescents. The idea that children are uniquely affected by armed conflict was brought to light through a study conducted by Graça Machel in 1996. The goal of this study was to document the number of ways that children are uniquely affected by and even targeted in situations of political violence and war. The report notes that in the decade leading up to 1996, 2 million youth had been killed, roughly 6 million had been injured, and countless others had been witness to or forced to participate in the violence associated with armed conflict. The report documents the myriad ways that armed conflict affects children. The most obvious loss is the thousands of children who are killed by bullets, land mines, and bombs among other weapons. Millions more experience the disruption of basic services and the destruction of family and community support systems, leading to physical and psychological trauma and even death. Even for children who do not experience the direct forms of violence brought on by armed conflict, the destruction of community relations, and increased distrust and insecurity that result, have lasting psychological consequences. The study report concludes with a long-term call to action that focuses on the societal and emotional roots of conflict as well as attempts to decrease arms delivered to conflict-ridden areas.

A follow-up study published in 2009 highlights the complexity of issues for children brought on by the nature of war and political violence across the globe. Although the follow-up report acknowledges advances made over the 10-year period, it also highlights the changing nature of war and how these changes increasingly put children in harm's way. "Over the past decade, conflict has impacted children more brutally than ever. They are victims of strikes against schools and of abductions aimed at forcing them to serve as combatants, sex slaves or servants. And in conflict zones their vulnerability is often greatly increased because violence claims their first line of defense – their parents" (UNICEF, 2007).

The study of children in these contexts has increased in number and scope, with an increasing understanding that war and political violence must be understood from multiple perspectives and with awareness that children are not just passive victims, but that their voices and active construction of their experiences must be considered in developing intervention efforts that include both goals of physical and mental well-being. The following article will review the changing nature of war, the myriad social, environmental, and psychological processes that are altered in contexts of war, and the documented effects of war and political violence on children. The section will conclude with a discussion of a move toward including children and adolescents' voices and perspectives in planning and implementing interventions and postconflict agreements.

The Changing Nature of War

The current article incorporates effects of a range of conflicts defined by different terms including political violence, war, ethnic conflict, intrastate conflict, armed conflict, sectarian violence and conflict, among others. Researchers have noted the decrease in interstate wars occurring globally with an increase in intrastate wars involving paramilitary groups and other nonstate actors since the middle of the twentieth century (UNICEF, 2009). The trend away from interstate conflicts involving national armies, and the emergence of smaller intrastate conflicts has increased the likelihood of the deliberate targeting of civilians, use of terrorism, and participation of civilian combatants. The results of these changes have several negative implications for children in particular. Bringing conflict off the battlefield and into communities results in the destruction of basic services, the tearing of the social fabric of communities, and most directly brings the violence associated with war and political violence into the daily lives of youth. As noted in the quote above, the changing nature of war has brought the violence and conflict associated with war and political violence closer to home for children influencing the environment that most directly impacts their well-being, the family system.

Context of War and Political Violence

Despite this recognition that children are uniquely affected by war and political violence, the research documenting these relations was limited for several decades. In the same year as the

original Machel study, Cairns and Dawes called attention to the need for psychological researchers to increase the scope and quality of research being conducted on children in contexts of political violence and war (Cairns and Dawes, 1996). Most of the research conducted to this time had a limited scope with the dominant outcomes of studies in these contexts being post-traumatic stress disorder (PTSD). Cairns and Dawes (1996) also note that research to that point supported the notion that a majority of children exposed to political violence and war did not develop clinical levels of symptomatology. Although results across conflicts suggest there is an increased risk for the development of emotional and behavioral problems in these contexts, positive outcomes are generally seen in most children, barring repeated exposure to severe events without emotional support. These results suggesting most children do not present with clinical problems encouraged researchers to consider resilience processes that may be at work. Research on children and political violence to that point suggested that research has focused too much on individual stress and coping processes focused on negative child outcomes. Cairns and Dawes also discussed the lack of longitudinal research conducted to date, limiting conclusions about the long-term effects of political violence and war as well as limiting our understanding of developmental processes at play for children in these contexts.

Since that call, the studies of children in these contexts has increased in number and scope. Given the noted limitations of the research on children and political violence at that point, Cairns and Dawes made recommendations for future research in this area, including the use of qualitative approaches that help researchers fully grasp the nature of violence as it is experienced and coconstructed by both children and adults, longitudinal research, and research conducted within developmental theory. They also noted the need to conduct research in places where peace agreements are established to better understand the role of systems of trust and reconciliation in establishing the intergroup relations that will surely affect postagreement stability.

This work along with the results showing a variety of both positive and negative responses to political violence motivated the development of theoretical models that help answer questions of developmental process, risk and protective factors, and a focus on resilience processes that can help explain why children in these contexts do not develop the expected high levels of psychopathology. New questions about what constitutes general well-being beyond the absence of psychopathology have also begun to emerge (Barber, 2013). Moreover, researchers are considering questions about cross-cultural differences in subjective well-being to better measure and document the ways that political violence and war affect children. In other words, the somewhat surprising low levels of psychopathology in war-affected communities may be related to the outcomes measured. Were researchers to identify and accurately measure culturally informed processes of well-being, we could gain a clearer picture of how political violence and war impact the lives of children.

War and political violence affect multiple elements of society, subsequently affecting multiple environments in which children develop. War and political violence disrupt basic services such as access to food and water, schools, religious institutions, health care facilities, and they can even cut children off from family members. It is because of these ubiquitous reverberating effects of war and political violence that researchers often adopt a social ecological model to understand the effects of war and political violence on children. The social ecological model describes the multiple overlapping contexts in which an individual lives and interacts (Bronfenbrenner, 1979). These levels include systems with which the developing individual directly interacts, such as the family system, peers, neighborhood systems, and schools. This model also recognizes the interplay between systems that might not directly influence the child, but that influence the systems in which the child is developing. For example, interactions between the school system and parent groups may impact the child through changes to school policy. The social ecological model also includes recognition of cultural systems and historical processes that shape the environment and interpretation of experiences. Finally, this framework recognizes the importance of change over time across all contexts.

Identifying the relevant factors at each of these levels of the social ecology is necessary for a thorough understanding of the effects of war and political violence on child development and well-being. For example, understanding the impact of exposure to community-level violence between conflicting nonstate actors requires understanding of the sociohistorical relations between the groups involved in conflict. The meaning behind the acts of violence between these groups will depend in part on timing, duration, and intensity of the conflict. For example, although there are similarities between intergroup conflicts, there exist critically important histories of relations between Palestinians and Israelis in the Middle East, or between Catholics and Protestants in Northern Ireland, or between Tutsis and Hutus in Rwanda, that must be understood and acknowledged to fully grasp the meaning of violence in these conflicts.

Identifying the full range of the effects of war and political violence on children requires an understanding of how both the child and their environment change over time. The development of mental and behavioral problems such as depression, anxiety, and aggression all take their own developmental course. At the same time, the communities in which children are developing in the face of war and political violence are also changing. Even for children who remain in their homes with intact families, the changes occurring around them will directly affect them or filter down to affect them over time. In some instances, changes will not be seen in children until years after conflict is over. Concern for children in these contexts is usually concentrated during the time that combat is occurring. Cairns and Dawes (1996) suggested that more research must be conducted on children after peace agreements are signed and children are left to deal with the broken environment that war and political violence leave behind. It is during these post-agreement periods, often time years after conflict exposure was experienced, that the consequences of the emotional, behavioral, and cognitive regulation to that exposure will come to fruition.

Mental Health and Psychopathology

Early studies of the effects of war and political violence on children focused on various forms of psychopathology such as

PTSD, depression, and anxiety. A recent review of the literature documented the effects of war on adolescents in multiple conflicts including those in Israel and Palestine, South Africa, Cambodia, Northern Ireland, Sri Lanka, Uganda, Kosovo, Croatia, Bosnia, and Herzegovina, among other places (Barber and Schluterman, 2009). The most frequently studied outcome of armed conflict is PTSD. Given the traumatic nature of events experienced during war, researchers have focused on PTSD with concerns that the violence experienced would disrupt children's ability to cognitively and emotionally process the events they experience leading to maladaptive responding that has long-term consequences for their physical and mental well-being. Relatedly, research has documented the increased risk for internalizing problems such as anxiety and depression for children exposed to war and political violence. Despite these findings across multiple conflicts, researchers have noted the relatively limited effect sizes and the number of studies finding null effects (Barber and Schluterman, 2009; Cairns and Dawes, 1996), suggesting that many children in these contexts show adaptive recovery from their experiences and the ability to use social support and other internal and external resources to overcome their experiences.

Aggression

A common concern regarding youth in contexts of war and political violence is the degree to which living in a violent community increases the likelihood of developing aggression and tendencies toward violence. In addition to the search for links between war and PTSD, depression and anxiety, much of the research on children and war has focused on aggression and related problems as an outcome of exposure to violence in these contexts. Many theoretical models within the social sciences would hypothesize that an increased exposure to violence would breed violent youth through processes such as modeling behavior, desensitization to violence, general increased physiological arousal, decreased moral development, and decreased cognitive processing of interpersonal information (Punamaki, 2009). Feelings of insecurity, distrust, and need for control can instill a sense of fear and defensiveness that motivates individuals to act aggressively as a form of self-protection (Staub, 2006). Although some research does suggest an increased risk for aggression and violence for children exposed to political violence and war, there are a number of individual differences that exist in this relationship. Research across contexts and conflicts has documented the increased risk for child development of aggression when they are exposed both directly and indirectly to war-related violence. At the same time, there are multiple individual- and contextual-level factors that either promote or deter the development of aggression in the context of violent conflict. Similar to the findings for the links between political violence and depression and anxiety, the studies linking war and political violence exposure to aggression in children has found limited and mixed effects.

Researchers are now looking to understand the multiple factors that explain this link along with the conditions under which children are most likely to develop problems with aggression in the face of political violence and war. As discussed above, the role of the family, and parents in particular are key variables in our understanding of the violence-aggression link. "In essence, the human mind is not merely a mirror for external violence; rather, children and adolescents construct their experiences according to the meanings given to them and the various social and psychological preconditions that accompany violence" (Punamaki, 2009: p. 74).

Identifying Risk and Protective Factors

Children affected by war and political violence show a range of outcomes across a large range of war-related situations. Given the heterogeneity of the issues, researchers have focused a great deal of attention on identifying specific factors that increase risk for negative outcomes while at the same time identifying specific factors that decrease risk for these same negative outcomes or those that increase the possibility of adaptive functioning. Risk and protective factors include factors about children themselves such as their gender and age during which the war exposure occurred, as well as factors external to the child such as their family environment, and other environments that contribute to or take away from the child's resources in dealing with the conflict they experience. Although many studies have examined individual characteristics like age and gender with many studies findings differences in responses for boys and girls and for children at various developmental periods, the findings are mixed, limiting the ability to make general statements about any overall impact of gender and age on children's responses to war and political violence. Regarding factors external to the developing child, research has focused on social support broadly defined. Receiving emotional support and guidance from families, schools, religious institutions, community groups among other organizations and individuals helps alleviate the effects of political violence and war on children making these systems critical to maintain and rebuild in the wake of conflict.

Another critical external factor for children exposed to political violence and war is the level of poverty of the family and surrounding community. War and political violence are also most likely to affect children living in poor communities (Cairns, 1996). The accumulation of stressful experiences for children in contexts of political violence has been shown to negatively affect children in poor environments due in part to a lack of financial and material resources, but also due to depleted emotional and family resources. Children living in low socioeconomic status conditions are more likely to experience negative effects of economic repercussions such as inflation, and research in other domains of child psychology have documented links between negative family environments and poverty suggesting that increased stress on the family system through war and political violence is more likely to affect those already in need.

The Role of the Family

It is widely understood that children develop in multiple social contexts with the family being the most proximal influence. Accordingly, much of the research examining for whom and under what conditions war and political violence affect

children examines the role of family members in the relations between violence and child development. The family unit experiences its own disruptions during war, and the break down of family bonds may even be a goal of tactics used in conflict. For example, as Cairns (1996) notes, the breaking of family relations was one of the tactics used by Pol Pot during the Cambodian genocide. In the fortunate circumstances when families do remain intact during war, parents' responses to the war and their children's exposure are thought to impact their children's responses to conflict. Commonly examined variables include parental responses to war, parenting variable such as parental warmth, and maternal and paternal psychopathology.

Several parenting variables have been examined as important to children's processing of stressful contexts. These variables include parental responsiveness, behavioral control, warmth, and acceptance. Research across contexts and conflicts has found that parents' mental health status has an impact on how children experience and react to political violence and war. Research across contexts such as Palestine and South Africa suggest that children are likely to suffer more negative outcomes in the face of war, if their mothers show signs of stressful responses such as posttraumatic stress symptoms (see Barber and Schluterman, 2009).

Intergroup Processes

Given the intergroup nature of many contexts of political violence and war, the effects of exposure to such violence will depend in part on the history of relations between the groups involved. Theorists and researchers across disciplines recognize that shared identification with groups is inherently a part of war and political violence (see Bar-Tal, 2007). Theories stemming from social psychology such as social identity theory and self-categorization theory describe psychological processes involved in the development and sustaining of negative intergroup attitudes.

The social identity paradigm (Tajfel and Turner, 1986) posits that the motivation for group members to positively differentiate their own group from relevant out-groups is partially driven by a need to achieve a sense of positive identity. Research has supported this idea showing that individuals with a stronger sense of identity with their in-group are more likely to have negative attitudes and behaviors directed at out-group members. Experimental studies have shown that the mere act of placing individuals into random groups is enough to create an increased likelihood for favoring in-group members and derogating out-group members. This experimental paradigm is known as the minimal group design. It follows that adding meaning to the groups with which we identify can increase the motivation to act negatively toward out-group members. In other words, if just being placed in an arbitrary group produces a natural motivation to act negatively toward out-group members, adding meaning, family ties, and history to these group memberships may increase the motivation to keep one's group in a higher, more power position than an opposing group. Adding the dimension of violence that is ethnically, religiously, or politically motivated to these naturally occurring intergroup processes clearly intensifies the motivations for the development of negative attitudes and the use of aggression against out-group members in contexts of political violence and war.

At the same time, children and adolescents gain support and meaning from their group and family connections, making the role of bonds to and identifying with the group complex as they relate to positive and negative responses to conflict. Individuals are more likely to give and receive social support from in-group members. Research has also shown that identifying with your ethnopolitical group that is part of the conflict, and understanding one's group's reason for participating in the conflict can help ameliorate the effects of experiencing violence associated with the conflict. This notion that group bonds play a dual role as both a benefit and a burden to positive child development is now being explored (Hammack, 2010). The results from studies across contexts such as Northern Ireland, Palestine, and Bosnia, suggest that the strength of identity with in-group members plays an important and powerful role in determining the behavioral, affective, and cognitive responses to exposure to intergroup conflict and violence for children.

Child Soldiers

Experience with political violence can take many forms. One of these forms in through participating in conflict as a child soldier or other forms of participation with armed groups. Recent estimates suggest that there are roughly 300 000 young people participating in armed forces or armed groups around the world (Betancourt et al., 2013). Youth in armed groups play a variety of roles including child soldiers, as sex slaves, spies, combatants, and laborers among other things. The conditions under which children are recruited and the experiences of child soldiers vary, paralleling the complexity of war experiences for children exposed to war and political violence outside of this particular experience. Children may be forced to participate in violent acts, taken from their homes, off the street or from orphanages, while others are recruited to join armed groups as a means of ensuring they are fed and protected. Child soldiers often go through a training period that may include witnessing and perpetrating killings, threatening, intimidating, or even killing other children in their group, and attacking civilians and villages. The Machel report discusses how the availability of small arms such as assault rifles and AK-47s have made it easier to recruit or force children and adolescents who can carry and use these weapons to join armed forces.

Research on child soldiers indicates that these children are at an increased risk of multiple mental health issues including PTSD, anxiety, and depression. The experiences of child soldiers are also greatly influenced by child gender. Girls often play particular roles as sex slaves, experiencing rape, impregnation, and high risk for sexually transmitted diseases. Girls are also at an increased risk with some studies suggesting lower levels of community acceptance after reintegration into their communities. In some cases, children are forced to take drugs such as amphetamines. Betancourt et al., 2013 recently conducted a review of relevant quantitative literature on child soldiers from 10 countries including Uganda, Sierra Leone, Liberia, Côte d'Ivoire, the Democratic Republic of Congo,

Mozambique, Nepal, Sri Lanka, El Salvador, and Germany. The review further documents the range of traumatizing experiences for youth in armed groups. Across conflicts high rates of children were exposed to violence through beatings, torture, and sexual abuse, and children perpetrated violence through injuring and killing others. Children were also exposed to violent attacks on family members and peers. Variables associated with decreased risk for children were family acceptance, social support, and educational/economic opportunities. In other words, children who have supportive families, opportunities for participation in the community through education and the ability to earn a living are more likely to show improvement in psychological functioning after reintegration. Research documenting the long-term adjustment of former child soldiers is limited and questions remain regarding the benefits of various elements of reintegration programs. The available research does suggest that, similar to the effects of other forms of exposure to political violence, family, and community support are key to helping youth adjust after they are reintegrated into their communities and families (Betancourt et al., 2013).

Treatment and intervention for child soldiers commonly include elements of Western approaches that focus on clinical approaches to trauma along with culturally grounded and community-based approaches. Many scholars in the area agree that the best approach includes multiple elements and supports for formerly recruited children across domains of functioning and society.

Intervention and Prevention Programs

Given the mixed findings regarding the outcomes for children in contexts of war and political violence, there is renewed interest in the question regarding what makes children resilient to these conditions. Resilience is a debated construct with different definitions and prerequisite conditions necessary within each definition. Recent reviews of the empirical literature on children in contexts of war and political violence suggest that the expected strong associations between child exposure to political violence and war and maladaptive outcomes in children are simply not consistently found (Barber and Schluterman, 2009).

As awareness of the needs of children in contexts of war and political violence has increased, researchers, clinicians, and local and international NGOs (nongovernmental organizations) have worked toward developing intervention programs specifically to meet the needs of this age group. Peltonen and Punamaki (2010) recently reviewed available literature in an attempt to evaluate the effectiveness of preventive intervention and treatment programs aimed at children exposed to armed conflict. Programs designed to reduce the negative impact of political violence on children utilized recommended treatment strategies and programs including cognitive behavioral therapy, trauma and grief focused therapy, along with other culturally and developmentally informed interventions including efforts to help alter attitudes out-group members, war, and peace. The limited number of experimental studies included in the review precluded the authors from making strong statements regarding the effectiveness of existing programs. From a subjective standpoint, the authors concluded that there is promise for programs that target youth with exposure to political violence; however, the dearth of experimental studies on the effectiveness of intervention programs limits the ability to make general recommendations for child-focused programming. Moreover, most of the evaluated methods of intervention were based in Western approaches that focus on individual mental health instead of utilizing culturally informed approaches that include traditional methods of understanding and treating mental health problems. There have been many criticisms of the use of individual-focused approaches such as cognitive behavioral therapy in cultures that use communal bereavement and treatment practices.

Although not specifically developed for youth exposed to war and political violence, other approaches based on the promotion of healing and reconciliation have shown positive effects on trauma symptoms and readiness to reconcile in postgenocide Rwanda (Staub et al., 2005). Staub and colleagues have also utilized radio programming to improve intergroup attitudes and behaviors, reflecting the notion that to be efficacious, interventions must target individuals, institutions, and cultural norms (Staub, 2006).

Developmental models must also continue to inform our understanding of how and when intervention should take place. Awareness of sensitive and critical periods of child development across social, cognitive, physical, and emotional domains should be considered in the development of programs for youth affected by war and political violence.

Youth as Victims, Perpetrators, and Agents for Social Change

Much of the recent research on children affected by war and political violence suggests that our understanding of the effects of war and peace-building must consider youths' voices and their active construction of their experiences. Children and young people make up a large portion of the world's population. Children and young people are active participants who can help society work toward positive social change. Moreover, analysis of recent conflict cycles of these intrastate conflicts suggests that conflict-ridden communities are likely to relapse into conflict (UNICEF, 2009). This pattern puts a concentrated focus on children and young people as key populations to target in reducing the relapse of communities into violent conflict. The break down of these cycles of conflict and relative peace must include a commitment by community members to solve disputes in nonviolent means. It is now recognized across international organizations such as the United Nations and nongovernmental organizations working to protect children and young people from the effects of war and political violence, that prevention of conflict or the relapse of conflict is the most promising means of protecting children. For peace-building efforts to be successful, programs must build and support capacities at multiple levels of the community and across domains of life. Sustained peace requires awareness of and programs targeting injustice and inequalities and a commitment to a culture of inclusion.

War Propaganda

Abstract

This article examines the development of theories of war propaganda in the twentieth and twenty-first centuries. Beginning with early theorists of war propaganda the article assesses the development of a 'science of propaganda' following World War I, before considering more recent works on war propaganda that focus particularly on the role of informal sources, such as the media. Finally, the article briefly assesses the role of propaganda during the 1991 Gulf War.

While the use of propaganda in situations of war and conflict is neither new nor novel, the systematic development of propaganda as an aspect of war machinery has been a development of the twentieth century. World War I (WWI) brought with it the need to coordinate support for war across large expanses of territory, to bolster the morale of troops, and to weaken the resolve of the enemy. States on both sides of the conflict thus invested in the production of propaganda on a large scale. Since the WWI, war propaganda has become increasingly complex, drawing from fields including marketing, public relations, social psychology, and political theory, and integrating lessons learned from previous war campaigns and scholarship on propaganda. Much of these developments can be identified in Gulf War propaganda. This article examines the evolution of knowledge on war propaganda through the theories of war propaganda that developed during the twentieth-century World Wars, and the later developments in propaganda research that focused on informal sources of propaganda, such as the mass media. Finally, this article will briefly look at the role of propaganda during the Gulf War.

Propaganda and WWI: Developing a Science of Propaganda

Propaganda is a notoriously difficult term to define. It has been variously understood as 'a direct attack against man' (Ellul, 1965), as the 'systematic mistreatment of truth and information and their procedural safeguards' (Cunningham, 2002), 'a mere tool' (Lasswell, 1937) and 'a practical process of persuasion' (Taylor, 1992). Nevertheless, all definitions of propaganda share a common understanding in relation to the purpose of propaganda – to direct public sympathies and attitudes. While the use of propaganda in this sense can be observed in most aspects of social life, from politics to public health campaigns, its use within wartime contexts requires special examination. As all democratic states require, at least, the appearance of public consent to engage in conflict, propaganda serves an essential purpose during war: it may be employed to gather support for entry into war, to maintain support for an on-going war, to justify or legitimize certain actions during war, to direct public sympathies toward some foreign groups or away from others, to dishearten enemy forces, encourage uprising against the enemy government or military, or to develop sympathy among the enemy nation for the invading nation, prior to invasion. The importance of propaganda to war is such that it has been argued that the battle for public opinion is as important during a war as the engagement of soldiers on the front (Hiebert, 2003: p. 243).

Tools and Techniques of Propaganda during the Great War

Propaganda may consist of rhetoric, images, music, national holidays, and other significant cultural symbols which are presented with the intention of directing public opinion. The use of such techniques and tools in situations of war and violent conflict are not new; rather, they have been identified in use since antiquity (Taylor, 2003[1990]) and are likely to have been in use since the beginning of organized warfare. However, a systematic study of techniques for directing public opinion in contexts of war did not develop fully until the beginning of the twentieth century. WWI, and the need to secure public support for the war on all sides, led to the development of modern war propaganda that borrowed techniques from the fields of marketing and public relations (Kingsbury, 2010).

Edward Bernays noted that it was "during the Great War, [that] the Nations realised the necessity of selling their national aims and policies" (Bernays, 1942: p. 6). All sides of the conflict engaged in propaganda as an integral aspect of the war effort and institutionalized the production of propaganda in government offices, including the German Central Office for Foreign Services, the British War Propaganda Board (also known as Wellington House), and the American Committee on Public Information (CPI). German and British propaganda targeted their own populations to raise morale and support for the war and to vilify the enemy, and targeted the enemy population to undermine morale and discourage support. Airdropped pamphlets and radio broadcasts were common tools for the dissemination of the WWI propaganda campaigns for Britain and Germany along with film, children's books, posters, and many other cultural products. However, both countries also targeted the US in the early years of the war as a potential ally (Murphy and White, 2007: p. 17). To this extent, the US acted, before 1917, as "a theatre of official propaganda combat between Britain and Germany" (Messinger, 1992: p. 22).

Unlike German and British war propaganda the target population for the American CPI was primarily US civilians who had shown reluctance to enter the war, although the CPI also distributed propaganda materials in neutral states and behind enemy lines. Drawing knowledge from the fields of public relations and marketing, the CPI disseminated messages that were simple, one-sided, and which portrayed the enemy in a highly prejudiced

fashion. These messages were disseminated via a wide range of materials, from pamphlets and books to educational materials, films, and speeches, including the Four-Minute Men addresses in which individuals delivered prowar/anti-German four-minute speeches at public gatherings. Although effective in achieving the support from the American populace for involvement in the war, these techniques also had a 'dark side' – Germans were largely vilified. Foreshadowing later wars, particularly the War on Terror where patriotism turned French fries into American fries, sauerkraut became known as liberty cabbage, and German-Americans experienced physical attacks and discrimination (Murphy and White, 2007: pp. 19, 20).

WWI brought the importance of propaganda as a tool of warfare to the fore; indeed, it has been described as "a bloody and relentless struggle in which sustaining morale became just as essential for both sides as sustaining the military effort" (Taylor, 2003: p. 176). Following WWI considerable investment was made to improve propaganda techniques, building on lessons learned during WWI. Although World War II (WWII) utilized the same tools for propaganda dissemination as were used in WWI, such as airdropped pamphlets, educational materials and radio broadcasts, a greater sophistication in the directing of public opinion was evident. 'Black operations' were used, for instance where sources of information were obscured in order to manipulate perceptions of events or news stories. During WWII, radio programs were broadcast by British propagandists who posed as German officers in order to spread false information or information to turn the populace against Hitler's regime (See for instance, Sefton Delmer's account of the British black propaganda radio campaign, 'Black Boomerang', 1962). Further, the use of censorship became increasingly important in controlling the flow of information to the mass media, while maintaining the appearance of an independent press. For instance, in Britain all commercial cables were routed to a single point where news was censored before being released to journalists and editors, who were then free to present and comment on the precensored news as they wished (Taylor, 2003: p. 213).

Theories of War Propaganda

In academic circles, WWI initiated an interest in the role of propaganda in war and scholars began publishing analysis of WWI propaganda thus ushering in the development of a 'science' of propaganda. Public opinion specialist and political advisor, Walter Lippmann contributed to the understanding of propaganda a psychological approach which recognized the connection between perception, ideas, and actions (Lippmann, 1998[1922]: pp. 29, 30). He writes, "those pictures [in one's head] which are acted upon by groups of people, or by individuals acting in the name of groups, are Public Opinion with capital letters" (Lippmann, 1998[1922]). Lippmann further argued that the press could not, and should not, be relied upon to deliver the news objectively, rather, he recommended that the press be directed by experts whose role was to organize public opinion for the press (1998[1922]: p. 30). Although criticized at the time for being too instrumentalist, Lippmann's ideas were highly influential; Ellul and Herman and Chomsky, for instance, built on his ideas regarding the mass media, although largely rejected the benefits perceived by Lippmann of elite or 'expert' interaction with the press.

Of the early works by authors including Bernays (1942), Lippmann (1922), and Bruntz (1938), Lasswell's *Propaganda Technique in the World War* (1927a) was among the most influential. Lasswell, building on Lippmann's psychological approach, put forward a value-free conception of propaganda as the "management of collective attitudes by the manipulation of significant symbols" (Lasswell, 1927b: p. 627). Lasswell's understanding of propaganda is significant for several reasons; first, he identifies that propaganda functions through the organization of culturally significant symbols including music, the national flag, art work, and words, in order to organize public attitudes (Lasswell, 1927b: p. 629). Secondly, Lasswell recognized the importance of the propagandist within situations of conflict and war. Indeed, Lasswell wrote that "the problem of the propagandist is to intensify the attitudes favorable to his purpose, to reverse the attitudes hostile to it, and to attract the indifferent, or, at the worst, to prevent them from assuming a hostile bent" (Lasswell, 1927b: p. 629). Thirdly, Lasswell understood propaganda to be deliberate and intentional. Lasswell's conceptualization of the function of propaganda in war had much in common with that of his contemporaries from the worlds of public relations and marketing; for instance, Bernays argued that propaganda involves the primarily elements: to heighten "the morale-unity of your own country, weaken the morale of your enemy and win over the morale of the neutrals" (1942: p. 237).

Lasswell's analysis of WWI propaganda led him to argue that there are six significant factors evident in successful war propaganda:

1. one must fasten guilt to the enemy for creating the contexts of war;
2. one must claim a unity of the people through claims to common history and favor by God and proclaim the inevitability of victory;
3. war aims must be clearly stated that appeal to culturally held ideals, such as freedom, peace, or security;
4. disseminating examples of the enemy's depravity serves to strengthen the belief that the enemy is responsible for the war;
5. unfavorable news should be cast as enemy lies in order to prevent disunity and defeatism;
6. horror stories that cast the enemy in poor light should be told, dehumanizing the enemy and thus justifying violent action (in Bernays, 1942: p. 236).

These factors, in one form or another, have formed the basis of most subsequent analysis of the content of propaganda messages.

German scholars also contributed to the understanding of propaganda. For instance, Hadamovsky, who later became Chief of Staff of the Nazi Party's Central Propaganda Office, wrote *Propaganda and National Power* (1933). Building on the work of Lasswell and others, he contributed a recognition of the potential of ridicule as, he argued, "to laugh at the enemy is as important as to fear his strength" (Hadamovsky, 1933) and the importance of the political sphere, the military and public opinion being presented as a unified will (Hadamovsky, 1933). Thus, he writes "those who direct a war must at the same time direct politics and public opinion" (Hadamovsky, 1933).

Critiquing and Detecting Propaganda: The Seven Devices of Propaganda

The success of American and British propaganda during WWI brought with it a fear of being manipulated by propaganda. Propaganda became largely associated with 'the enemy' as opposed to an expectation of objective reporting and information dissemination from one's own country. In the US, interest grew among the public in developing skills to detect enemy propaganda. The Institute of Propaganda Analysis (IPA) published a framework for the analysis of propaganda in 1937. The framework laid out the following seven common propaganda devices (from Sproule, 2001):

1. *Name-calling* – attaches negative associations through the use of pejorative words and labels "to those individuals, groups, nations, races, policies, practices, beliefs, and ideals which he would have us condemn and reject."
2. *Glittering generalities* – "virtue words" such as "truth, freedom, honor, liberty, social justice, public service, the right to work, loyalty, progress, democracy, the American way, Constitution defender" are used to associate the propagandists' viewpoint with attitudes and ideas that are positively perceived.
3. *Transfer* – "the propagandist carries over the authority, sanction, and prestige of something we respect and revere to something he would have us accept." Sproule notes that "efforts to establish identification between a political project and the audience's reverence for national or religious symbolism" were common forms of transfer (2001: p. 136).
4. *Testimonial* – links the propagandists' position to some specific, favored person or institution, thereby associating their program or ideas with the positive associations already established with the person or institution.
5. *Plain folk* – As Sproule explains, "Persuaders and leaders present themselves as 'just plain folks' to establish an identity with ordinary Americans" (Sproule, 2001).
6. *Card stacking* – overemphasis and underemphasis are used to draw attention to some 'truths' and distract from others, in order to direct public opinion in such a way "that the audience forgets inconvenient information and embraces half truths" (Sproule, 2001).
7. *Band wagon* – The propagandist presents information so that it appears to be already accepted and thus to have people "follow the crowd," because "everybody's doing it" (Sproule, 2001).

Although criticized following WWII as being overly simplistic and adding little to Lasswell's analysis (Sproule, 2007: p. 131), the framework has made a lasting impression through its digestible rhetoric and easy application to propaganda content, and has been reinvigorated more recently through analysis of the Gulf War and the War on Terror.

Propaganda in the New World Order: The Growing Significance of Informal Sources of Propaganda

As in the World Wars, propaganda was an essential tool of the Cold War. While Soviet propaganda remained primarily a product of the State, the U.S. public demonstrated little tolerance for direct state-issued propaganda. Indirect control or covert control of information thus became an increasingly important aspect of propaganda in the US. Television news programs were particularly important tools for propaganda during the Cold War, with the state tightly controlling the flow of information which was reported by ostensibly independent news programs (Bernhard, 1999: pp. 4–6).

Since the 1970s scholarly interest in war propaganda has focused increasingly on the role of the news media and capacity for news corporations and journalists to deliver information independent from the interests of the state (Jowett and O'Donnell, 1992). While a number of authors have studied the role of the media in the dissemination of propaganda during periods of war and conflict, including Ellul (1965), Galtung and Vincent (1992), Jowett and O'Donnell (1992), and Schecter (2003), the Propaganda Model developed by Edward Herman and Noam Chomsky (1988) presents the most significant development in the analysis of the media's role in war propaganda in democratic states.

The Propaganda Model

Written during the Cold War, the Propaganda Model developed by Herman and Chomsky (1988) examines news media behavior in relation to state interests, calling into question the notion of the media as a 'fourth estate' tasked with holding government powers in check (Klaehn and Mullen, 2010: p. 12) and is applicable to states in which the news media is under corporate rather than state control. Rather, Herman and Chomsky argue that the media often reflects the interests of the economic and political elite, although "it is much more difficult to see a propaganda system at work where the media are private and formal censorship is absent" (1988: p. 1). The Propaganda Model sets out a series of five 'filters' which they argue act to cleanse the news of dissenting views, attitudes, and information via money and power. The filters are

1. the size, concentrated ownership, owner wealth, and profit orientation of the dominant mass-media firms;
2. advertising as the primary income source of the mass media;
3. the reliance of the media on information provided by government, business, and 'experts' funded and approved by these primary sources and agents of power;
4. 'flak' (i.e., negative responses) as a means of disciplining the media; and
5. 'anticommunism' as a national religion and control mechanism. (It is reasonable to now argue that anticommunism has been replaced by anti-Islamism as a control mechanism (see, for instance, Brown, 2008)).

Thus, in the context of the Cold War, Herman and Chomsky argue that "these elements interact with and reinforce one another. The raw material of news must pass through successive filters, leaving only the cleansed residue fit to print. They fix the premises of discourse and interpretation, and the definition of what is newsworthy in the first place, and they explain the basis and operations of what amount to propaganda campaigns" (1988: p. 2). Herman and Chomsky's model importantly contributes to the understanding of war propaganda a method for analyzing how an apparently independent mass media acts to reproduce the interests of the state and economic elites. In

terms of war propaganda this is particularly significant as it helps to explain how support for war can be created and maintained by the state, through an 'independent' mass media. As will shortly be examined, the first Gulf War presents one of the most significant examples of the mass media's role in disseminating prowar propaganda.

Propaganda and the Gulf War

As this article has argued, the World Wars established the contexts for the use of propaganda on a massive scale to garner support for war and to demoralize the enemy. It also created the contexts through which successful and unsuccessful propaganda could be studied leading to scholarship on war propaganda that drew from the World War experiences and incorporated knowledge from diverse fields, including public relations, marketing, and political science. This work has produced a compendium of factors evident in war propaganda. Across the various listings of factors, devices, and elements, there are several common aspects identifiable including: the need to establish a clear enemy, to present war as a just cause, to attach sentiments favorable to the war effort to positively perceived attitudes such as patriotism or liberty, and to reach the enemy with information that will act to negate attitudes of resistance and sway the general enemy populace toward views favorable to their enemy (see for instance, Bernays, 1942; Sproule, 2007). Herman and Chomsky (1988) further provide a method for understanding how power and wealth creates filters through which news is cleansed of information that may go counter elite interests. These tools provide the potential to better understand the function and form of war propaganda. In the following section, American propaganda during the Gulf War, disseminated by both the state and the news media, will be considered as it relates to the above factors.

Establishing the Enemy/Attaching Guilt

Harold Lasswell argued that war propaganda must, in the first instance, attach guilt to an enemy as an essential factor in directing public opinion toward prowar sentiments (1927a). Hadamovsky added that ridicule was as important as fear in portraying the enemy in a poor light (1933) while the IPA noted the role of 'name-calling' in war propaganda (Sproule, 2001: p. 136). In the lead up to, and during, the Gulf War Saddam Hussein became the target of ridicule, name-calling, and blame for the war; indeed, Saddam Hussein became perhaps the most vivid symbol of the Gulf War.

From 2 August 1990, the day Iraq invaded Kuwait, numerous articles describing Hussein, his past, his character, even his physical appearance appeared in newspapers in America. A brief scan of the New York Times between 3 and 5 August reveals Hussein as a 'megalomaniac' (Sick, 1990: p. 1), 'paranoid,' 'a mad bull,' 'coldly calculating,' and 'ruthless' (Lewis, 1990: p. 1) and comparisons with Hitler and the Blitzkrieg abounded. In President Bush's Address on the Invasion of Kuwait (1990b), he draws a connection between America's role in defending Kuwait against Hussein's aggression and America's role in defending Europe against Hitler, stating, "As was the case in the 1930's, we see in Saddam Hussein an aggressive dictator threatening his neighbors." The depictions of Hussein that centered on insanity and aggressive irrationality were important not only in creating a negative perception of Hussein but also in cementing support for Bush's position as a wartime leader. Bush further identifies Saddam Hussein and his actions as the cause of the war. He claims that Hussein had 'promised' not to invade Kuwait (Bush, 1990b). In this way, Bush's speech puts the guilt for starting the war squarely on the shoulders of Saddam Hussein and thus largely absolving the American populace of any such guilt.

However, as Hadamovsky noted, ridicule is also an important device of war propaganda. This was also mobilized during the Gulf War in relation to Hussein who featured heavily in cartoons, comedy sketches such as Saturday Night Live, even popular films, like 1991's Hot Shots! featuring a feminized Hussein lounging beside his pool with a cocktail, and in political speeches and newspaper articles. Such a characterization of the leader contributed toward the dehumanization of Hussein and ultimately to the rallying of support for the Gulf War (Conners, 1998: p. 96). The negative portrayal of Hussein was so successful that one commentator described Hussein as "George Bush's secret weapon in bringing about the war" (Mueller, 1993: p. 203).

Just Cause for War

Atrocity stories are a common feature of war propaganda. Such stories help to dehumanize the enemy, linking them with acts and attitudes that are unimaginable to the audience. This creates the conditions in which individuals are more likely to support entering into, or maintaining, a war. Images of past atrocities began to surface in newspapers after Iraq's invasion of Kuwait, including pictures of Kurdish children slaughtered with nerve gas. News agencies disseminating these images neglected to mention that its component parts may have been purchased through agricultural grants from the U.S. and that the helicopters used to spray the gas were American-made and purchased, or that President Reagan blocked the passing of a bill that would have punished similar attacks by cutting Iraq off from U.S. loans, military and nonmilitary assistance, credits, credit guarantees, and items subject to export controls (Hurd and Rangwala, 2001: p. 1), demonstrating an instance of what Sproule calls 'card-stacking' (Sproule, 2001: p. 136). One particularly inflammatory story about Iraqi soldiers pulling infants out of incubators in a hospital in Kuwait and throwing them on the ground to die elicited huge public outrage and was used no less than six times in a single month by George H.W. Bush to point out Saddam's ruthless and despicable nature, before the story was exposed as a lie. Nevertheless, the story was successful propaganda: it has been credited with swaying public opinion toward support of the war (Cohen, 1992: p. 1).

Positive Associations

On 11 September 1990, Bush addressed a joint session of congress. He stated in the opening paragraph of his speech that "following negotiations and promises by Iraq's dictator Saddam Hussein not to use force, a powerful Iraqi army invaded its trusting and much weaker neighbour Kuwait"

(Bush, 1990a: p. 1). The representation of a 'rich' and 'powerful' Iraq invading a 'smaller' and 'peaceful' Kuwait (Bush, 1990b) was used to create the semblance of a just war in which America was defending the weak, thus associating the war with positive notions of honor, liberty, and freedom. In Bush's 11 September 1990 speech he praised the service men in the Gulf, describing them as brave, well-trained, and dedicated and states, "if there was ever a time to put country before self and patriotism before party, the time is now" (Bush, 1990b: p. 2). This statement conflates patriotism with support for the war and dissent with selfishness. He goes on to state that America was defending "civilized values around the world" (Bush, 1990b), invoking the familiar concept of America's grand role as a civilizational force and thus its duty to defend 'civilization' when under threat. Indeed, as Allen et al.'s study of media framing in the Gulf War indicates, media coverage gave primary emphasis to themes that conflated patriotism, militarism, and nationalism (1994: p. 272). Bush's statements also reassured a skeptical population that the war was right, just, and moral. The common use of terms such as patriotism, civilization, liberty, freedom, and honor are, indeed, 'glittering generalities' as described by the IPA (Sproule, 2001: p. 136) which bring with them positive associations that help to obscure the complex and often distressing facts of the war and attach positive sentiment to the position of the speaker. In this way, the use of positive terms in association with the prowar position was an effective technique of Gulf War propaganda.

Demoralizing the Enemy

A further essential aspect of war propaganda, according to Bernays (1942: p. 237), is the demoralization of the enemy. American Gulf War propaganda did not shy from engaging in this aspect of propaganda. Efforts to demoralize the enemy during the Gulf War included the dropping of leaflets that resembled Iraqi Dinar but printed with the title of 'Safe Conduct Pass' informing the recipient that they 'do not have to die' if they lie down their weapons and cease resistance. Radio broadcasts, megaphone announcements, and pamphlets were also used to demoralize the Iraqi army and civilian populace and quell resistance. The effectiveness of the U.S. campaign to demoralize the Iraqi 'enemy' was described by one U.S. Colonel as follows:

> PSYOP [psychological operations] messages persuaded approximately 44 percent of the Iraqi army to desert, more than 17,000 to defect, and more than 87,000 to surrender… radio broadcasts and leaflets, helped cause the defection, desertion and surrender of some 40,000 Iraqis — all without firing a shot.

> Jones, 1994: p. 22

The Role of the News Media in Gulf War Propaganda

The Gulf War presents an exceptional opportunity to examine the role of the news media in disseminating state propaganda. Because of the nature of this war that was largely fought in the air and because of military regulations, the press depended on military briefings to gain information (Jacobs, 1992) and news was thus filtered prior to receipt by news-stations, similar to the experience of the news media in Britain during WWII. This limited the press' ability to engage directly with the war, but left them to relate the appearance of the war to an audience at home. However, the importance of appearance in the Gulf War was not limited to reporting on the war itself; securing the public approval for the Gulf War also depended heavily on the *appearance* of approval at home.

Despite massive antiwar protests and even polls that suggested that a plurality of Americans actually supported the notion of allowing Iraq to retain a portion of Kuwait in exchange for peace (Mueller, 1993: p. 203), the media continued to insist that the majority of Americans supported military intervention in Kuwait. Protests received little airtime and when protesters were shown, were portrayed as "untrustworthy, dishevelled, non-conforming 'others'" (Allen et al., 1994: p. 273). In fact, of the 2855 minutes of television coverage of the Gulf crisis between 8 August 1990, and 3 January 1991, only 29 minutes or 1% covered popular opposition (Allen et all., 1994: p. 257). The media suppression of dissent helped consolidate a view of unity within the nation, such that a 'unified will' was presented, conforming to the advice for successful propaganda by Hadamovsky (1933) and Lasswell (1927a) and the notion of the 'band wagon' by the IPA. This theory largely compares with Noelle-Neumann's Spiral of Silence (1984) hypothesis which argues that individuals will self-censor views that they perceive as unpopular so as to avoid social retribution and isolation resulting in a spiral of silence.

The media, in presenting the Gulf War as one that received tremendous approval (Kellner, 1992: p. 1), appears to have played a significant role in actually securing this approval through a band wagon or united will effect. Although the public was initially disinclined to engage in war, on 16 January 1990, polls demonstrate a sudden shift toward support for military action (Allen et al., 1994: p. 255). In reviewing Paletz analysis of the media in the Gulf War through the lens of the Propaganda Model, Herring and Robinson identify where the Propaganda model can be implicitly identified, shown by Herring and Robertson below in square parenthesis:

> Insufficient dedication to the freedom of the press, fear of provoking governmental outrage [the flak filter of the propaganda model], shared frames of reference with governing elites [the ideological filter of the propaganda model], and the pursuit of sales and ratings [the advertising filter of the propaganda model] are among the factors that can help explain the acquiescence to government curbs, no matter how reluctant, of media executives.
>
> Herring and Robinson, 2003: p. 560

In this analysis, the media thus appears as a tool of propaganda. Through the expectation of independence, the public largely accords the mass media a special status as 'testimonial,' thus permitting the dissemination of information as neutral. However, as information passes through various filters, the state and corporate elites (often aligned) strip the news of information harmful to their position. Nevertheless, through reference to their special status, the media dissemination of selected information which reflects elite interests, acts to create the appearance of a unified will which the public will fall in line with. In contexts of war and conflict, the news media is therefore an important source of propaganda, with the capacity, as

described in relation to the Gulf War, to direct public opinion in a significant ways.

The Potential of War Propaganda

This article has provided a brief examination of a selection of the most influential scholars of war propaganda in the twentieth and twenty-first centuries. War propaganda is both a contributor, and a response, to war and conflict and scholarship on war propaganda demonstrates both these impulses: it has attempted to advance the success and possibilities of propaganda to support war efforts and to establish the means to recognize and counter propaganda. While the early twentieth-century theorists of war propaganda analyzed the form and function of propaganda commonly perceiving it as a neutral tool to be used to direct public opinion, propaganda took on an increasingly negative image following WWI and analysis began to focus rather at defending against or deciphering propaganda. Most recently, the behavior of the mass media and non-state sources of war propaganda have been the focus of scholarly inquiry. The growth of social media as a tool for the dissemination of war propaganda will no doubt spawn new theories and models among scholars of propaganda. Nevertheless, what is shared by the approaches to the study of war propaganda is the recognition that propaganda is a significant aspect, and tool, of war.

Abstract

The sociology of war is a central topic in both political and historical sociology, since war is one of the most important policies states can pursue, and the outcomes of wars have often shaped both the formation and the dissolution of states. The literature on war is thus concerned with both its causes and its consequences. Studies of the causes of war can be divided into three broad categories. The first type takes the system as a whole as the unit of analysis and focuses on how characteristics of the interstate system affect the frequency of war. States are the unit of analysis in the second type, which explores the relationships among political, economic, and cultural features of particular states and their propensity to initiate wars. The third type analyzes war as an outcome of choices made by individual and small-group decision making. Theories of the consequences of war tend to focus either on its role in state formation, or on its causal impact on internal revolts and revolutions. Historical sociologists have shown that the frequency, duration, and timing of medieval and early modern warfare were the most important determinants of the size and structure of states. However, just as war can make states, it can break them too. Costly warfare often leads to fiscal crises and state breakdown, facilitating revolutions.

The sociology of war is a central topic in both political and historical sociology, since war is one of the most important policies states can pursue, and the outcomes of wars have often shaped both the formation and the dissolution of states. The literature on war is thus concerned with both its causes and its consequences.

Studies of the causes of war can be divided into three broad categories. The first type takes the system as a whole as the unit of analysis and focuses on how characteristics of the interstate system affect the frequency of war. Debates focus on characteristics of the interstate system that are thought to increase or decrease war, such as global economic cycles, balances of power, and the increasing role of transnational organizations such as the United Nations. States are the unit of analysis in the second type, which explores the relationships among political, economic, and cultural features of particular states and their propensity to initiate wars. Social scientists disagree about the effects of political systems (democracy vs. autocracy) and economic systems (capitalist, socialist, or other) within states on war. The third type analyses war as an outcome of choices made by individual and small-group decision making. There is also no consensus on which model of individual decision making is most appropriate for the study of war. Is the decision to go to war based on a rational calculation of economic costs and benefits, or is it an irrational outcome of distortion in decision making in small groups and bureaucracies?

Theories of the consequences of war tend to focus either on its role in state formation, or on its causal impact on internal revolts and revolutions. Historical sociologists have shown that the frequency, duration, and timing of medieval and early modern warfare were the most important determinants of the size and structure of states (Tilly, 1975, 1990; Ertman, 1997). However, just as war can make states, it can break them too. For example, Skocpol (1979) argues that costly warfare often leads to fiscal crises and state breakdown, facilitating revolutions.

Causes of War: The Interstate System

Most studies of war that take the interstate system as the unit of analysis begin with assumptions from the 'realist' paradigm. States are seen as unitary actors, and their actions are explained in terms of structural characteristics of the system. The most important feature of the interstate system is that it is anarchic. Unlike politics within states, relations between states take place in a Hobbesian 'state of nature.' Since an anarchic system is one in which all states constantly face actual or potential threats, their main goal is security. Security can only be achieved in such a system by maintaining power. In realist theories, the distribution of power in the interstate system is the main determinant of the frequency of war.

Although all realist theories agree on the importance of power distribution in determining war, they disagree about which types of power distributions make war more likely. Balance-of-power theories (Morgenthau, 1967) suggest that an equal distribution of power in the system facilitates peace and that unequal power distributions lead to war. They argue that parity deters all states from aggression and that an unequal power distribution will generally result in the strong using force against the weak. When one state begins to gain a preponderance of power in the system, a coalition of weaker states will form to maintain their security by blocking the further expansion of the powerful state. The coalitions that formed against Louis XIV, Napoleon and Hitler seem to fit this pattern.

Hegemonic stability theory (Gilpin, 1981) suggests exactly the opposite, that unequal power in the system produces peace and that parity results in war. When one state has hegemony in the world system, it has both the incentive and the means to maintain order in the system. It is not necessary for the most powerful state to fight wars, since their objectives can be achieved in less costly ways, and it is not rational for other states to challenge a hegemon with overwhelming power. For example, the periods of British and US hegemony were relatively peaceful and World Wars I and II occurred

during intervening periods in which power was more equally distributed. A related attempt to explain great-power war is power transition theory (Organski, 1968). Power transition theory suggests that differential rates of economic growth create situations in which rising states rapidly catch up with the hegemonic state in the system, and that this change in relative power leads to war.

Debates about power transitions and hegemonic stability are of much more than theoretical interest in the contemporary world. Although the demise of the USSR has left the USA as an unchallenged military hegemon, its economic superiority is being challenged by the European Union and emerging Asian states (Japan in the short run, perhaps China in the long run). If power transition and hegemonic stability theories are correct, this shift of economic power could lead to great power wars in the near future.

Another ongoing debate about systemic causes of war concerns the effects of long cycles of economic expansion and contraction. Some scholars argue that economic contraction will increase war, since the increased scarcity of resources will lead to more conflict. Others have suggested the opposite: major wars will be more frequent during periods of economic expansion because only then will states have the resources necessary to fight. Goldstein's (1988) research suggests that economic expansion tends to increase the severity of great-power wars but that economic cycles have no effect on the frequency of war.

One significant change in the last half of the twentieth century which will require substantial revisions in realist systemic theories of war is the development and increasing power of transnational organizations (such as the United Nations), since their assumption that the interstate system is anarchical may no longer be valid. If the military power of the United Nations continues to grow, it could become more and more effective at preventing wars and suppressing them quickly when they do start. Of course, it remains to be seen whether powerful existing states will choose to cede more power to such institutions.

Theoretical debates about the systemic causes of war have not been resolved, in part because the results of empirical research have been inconclusive. Each theory can point to specific cases that seem to fit its predictions, but each must also admit to many cases that it cannot explain. Part of the problem is that systemic theories have not incorporated causal factors at lower levels of analysis, such as internal economic and political characteristics of states. Since the effects of system-level factors on war are not direct but are always mediated by the internal political economy of states and the decisions made by individual leaders, complete theories of the causes of war must include these factors as well.

Causes of War: Capitalism and Democracy

One of the longest and most heated debates about the causes of war concerns the effects of capitalism. Beginning with Adam Smith ([1776]1976), liberal economists have argued that capitalism promotes peace. Marxists (Lenin, [1917]1939), on the other hand, suggest that capitalism leads to frequent imperialist wars.

The Smithian liberal argument suggests that since capitalism has both increased the benefits of peace (by increasing productivity and trade) and the costs of war (by producing new and better instruments of destruction), it is no longer rational for states to wage war. The long period of relative peace that followed the triumph of capitalism in the nineteenth century and the two world wars that came after the rise of protectionist barriers to free trade are often cited in support of liberal economic theories (but the same facts can be explained by hegemonic stability theory as a consequence of the rise and decline of British hegemony).

In contrast, Marxists (Lenin, [1917] 1939) argue that economic problems inherent in advanced capitalist economies create incentives for war. First, the high productivity of industrial capitalism coupled with a limited home market due to the poverty of the working class result in a chronic problem of 'underconsumption.' Capitalists will thus seek imperial expansion to control new markets for their goods. Second, capitalists will fight imperialist wars to gain access to more raw materials and to find more profitable outlets for their capital. These pressures will lead first to wars between powerful capitalist states and weaker peripheral states, and next to wars between great powers over which of them will get to exploit the periphery.

With the increasing globalization of economics, and the transitions of more states to capitalist economies, the debates about the effects of capitalism, trade, and imperialism on war become increasingly significant. If Adam Smith is right, our future is likely to be more peaceful than our past; but if Marxist theorists are right, we may see economically based warfare on an unprecedented scale.

The form of government in a country may also determine how often it initiates wars. Kant ([1795]1949) argued that democratic states (with constitutions and separation of powers) will initiate wars less often than autocratic states. This conclusion follows from a simple analysis of who pays the costs of war and who gets the benefits. Since citizens are required to pay for war with high taxes and their lives, they will rarely support war initiation. Rulers of states, on the other hand, have much to gain from war and can pass on most of the costs to their subjects. Therefore, when decisions about war are made only by rulers (in autocracies), war will be frequent, and when citizens have more control of the decision (in democracies), peace will generally be the result.

Empirical research indicates that democratic states are less likely than nondemocratic states to initiate wars, but the relationship is not strong (Kiser et al., 1995). Perhaps one reason for the weakness of the relationship is that the assumption that citizens will oppose war initiation is not always correct. Many historical examples indicate that in at least some conditions citizens will support war even though it is not in their economic interests to do so, due to nationalism, religion, ethnicity, or other cultural factors.

Perhaps the most interesting current debate about democracy and war surrounds the proposition that democratic states never fight each other. There is clearly a strong empirical generalization to be explained, since all agree that democratic states rarely fight each other – depending on exactly how 'democracy' and 'war' are defined, some argue they never do (Weart, 1998). However, scholars disagree about the causal mechanism responsible for this association. Some stress the role of political culture, arguing that the norms of toleration and mutual accommodation that prevent conflicts within

democracies from escalating to violence have the same effect in limiting violent conflicts between democracies. These states consider each other part of the same 'ingroup' sharing the same values, and are thus very unlikely to fight. In contrast, others suggest that 'democratic peace' could be the result of rational self-interest. Democratic politicians may simply fear the negative impact that losing a war might have on their prospects for re-election. Further research, probably at the level of detailed case studies that can reveal precise causal mechanisms, will be necessary to resolve this debate.

Causes of War: Decision Making

Few theories of war focus on the individual level of analysis; their assumptions about individual decision making are usually implicit or undeveloped. Notable exceptions include rational choice theories (Bueno de Mesquita, 1981, Bueno de Mesquita and Lalman, 1992) and arguments about organizational and small group decision making (Allison, 1971).

Bueno de Mesquita begins by assuming that the decision to initiate war is made by a single dominant ruler who is a rational expected-utility maximizer. Rulers calculate the costs and benefits of initiating war, and the probability of victory, so wars will be initiated only when rulers expect a net gain from them. These assumptions generate several counterintuitive propositions. For example, common sense might suggest that states would fight their enemies and not their allies, but Bueno de Mesquita (1981) argues that war will be more common between allies than between enemies. Wars between allies are caused by actual or anticipated policy changes that threaten the existing relationship. The interventions of the USA in Latin America and of the USSR in Eastern Europe since World War II illustrate the process. Other counterintuitive propositions suggest that under some conditions a state may rationally choose to attack the stronger of two allied states instead of the weaker, and under some conditions it is rational for a state with no allies to initiate war against a stronger state with allies.

Other analyses of the decision to initiate war focus on how the social features of the decision-making process lead to deviations from rational choice. Allison (1971) argues that standard operating procedures and repertoires within states tend to limit the flexibility of decisions and make it difficult to respond adequately to novel situations. Others focus on the small groups within states (such as executives and their cabinet advisers) that actually make decisions about war. The cohesiveness of these small groups often leads to a striving for unanimity that prevents a full debate about options and produces a premature consensus. In spite of these promising studies, work on the deviations from rational choice is just beginning, and we are still far short of the general microlevel theoretical model of the decision to initiate war.

Consequences of War: State Formation and Bureaucratization

How and to what extent does war affect the formation and the structure of states? Tilly (1975, 1990) argues that 'war made states' in the early modern era. Warfare (along with the repayment of debts from past wars) cost far more than any other state policies in early modern Europe. Moreover, the timing and the nature of war shaped the structures of these developing states.

One of the most interesting ongoing debates concerns whether war facilitates or hinders bureaucratization. Weber ([1922]1978) argued that states involved in military competition with other states (e.g., Western Europe) would be more likely to bureaucratize than those that were more isolated (e.g., China, Japan). Although he does not use this terminology, he basically argues that states not facing the threat of war would be satisfied with existing administrative arrangements, whereas those competing militarily would be forced to adopt the more efficient bureaucratic form.

In contrast to this, Levi (1988) views war as a consistent impediment to bureaucratization. She argues that war raises the discount rates of rulers, causing them to pursue policies that provide immediate gains even if they are costly in the long term. Thus, rulers facing war would be unlikely to pay the high start-up costs of bureaucratization, but would instead do things like selling offices which would make bureaucracy much more difficult to implement.

Ertman (1997) suggests a related argument in which the timing of war is important. When states experienced early sustained warfare (prior to about 1450) they developed patrimonial administrations (due to lack of trained personnel and the dominance of 'cultural models' derived from feudal and Catholic institutions). These institutions were very difficult to bureaucratize due to the power of entrenched officials to block reform. Ertman argues that states that were able to avoid frequent war until later were able to develop more bureaucratic administrations.

Finally, wars that result in severe losses may facilitate bureaucratic reforms. One of the main barriers to bureaucratization is the entrenched officials in the state administration who have both the incentives and the power to block reform (Ertman, 1997). These officials will not be dislodged by most wars, but their power will be broken by a severe loss at war, especially one that results in foreign occupation.

Consequences of War: Revolt and Revolution

Since the classic work of Simmel ([1908]1955, pp. 98–99) and Coser (1956, pp. 19, 95), the conventional wisdom has been that wars decrease the probability of revolts by increasing the internal cohesion of societies (the 'ingroup-outgroup' or 'conflict-cohesion' hypothesis). However, the results of empirical tests of the relationship between revolt and war have been mixed, at best.

In contrast to the 'conflict-cohesion' hypothesis, historical sociologists focusing on the early modern period (Tilly, 1975, p. 74) argue that fighting wars increased the likelihood of revolts. Tilly argues that since subjects had few institutionalized mechanisms available to stop rulers from initiating wars contrary to their interests, the only option they had to try to limit war was revolt. In addition, Tilly (1975, p. 74) notes that since participating in wars weakens rulers, it increases the likelihood of a revolt.

Theda Skocpol (1979) has made the most compelling argument that war is a primary cause of major 'social revolutions.' Her argument about the origins of the French, Russian, and Chinese revolutions stresses the importance of factors that weaken the state, making it more vulnerable to overthrow. The main factor that tends to weaken states is war, especially in the context of strong peasant communities and an alienated dominant class. This work has been the primary inspiration for the development of a 'state-centered' approach to historical sociology.

Conclusion

This short summary has only been able to scratch the surface of the voluminous literature on war. Future research should attempt to link the several topics discussed here, by bringing together the micro and macro causes of war, and by tying the causes more closely to the consequences of war. The increasing development of technologies of mass destruction and the rise of transnational political units will also challenge existing theoretical frameworks. Like most of sociology, the sociology of war is still in its infancy.

Abstract

Organized, collective violence has rarely been seen as a driving force in societal development and, consequently, warfare has been a neglected object of investigation. In recent years, sociology have become increasingly interested in war and its implications for society. In particular, scholars within the field of historical and comparative sociology address the issue. This article argues that sociology of war must focus on the relationship between the units waging war and the implications of warfare for societal development. These units are political orders of all kinds (most often we call them states) but inspired by Norbert Elias (1897–1990) here they are called survival units. The core of sociology of war concerns the study of the consequences of war in relation to the stability and/or change of state and society.

Introduction

War seems to be one of the few constants in human history. This has not, however, been reflected in the history of social thought in general nor in sociology in particular. We do find, however, some reflections on collective violence and war in classical social thought (from Thomas Hobbes (1962) to Max Weber (1980, 1991)) but war as such has never been an established object of investigation for sociological research. In the postwar period, in particular, war and collective violence have almost been omitted from the sociological agenda. It is significant that both collective violence within societies and between states are ignored as important social phenomena. In recent years, however, war has gained more interest partly due to 11 September 2001 and the implications (wars in Afghanistan and Iraq, terrorism) and partly due to a renewed interest in the relationship between warfare and state formation processes.

Thus sociology of war as a research field and a subdiscipline has developed fairly recently. How come that war for many decades was almost neglected by sociologists? The omission of war and politically organized violence in sociology and social theory can be seen as a consequence of social theory and sociology being embedded in liberalism and Marxism. Liberalism and Marxism are both worldviews, which promise us a world without violence. Michael Mann (1988) and more recently Hans Joas and Wolfgang Knöbl (2013) have pointed to this explanation. Liberalism argues that an increasing global division of labor and stronger interdependence between nations will reduce the incentives for warfare. Marxism argues along the same line but adds that conflicts will disappear in the communist society when classes are dissolved.

This seems to be a plausible explanation but it must be added that the neglect of violence and warfare in social theory also originates in a specific conceptualizations of society – the key concept in classical social theory. Society is seen as a fusion of its internal elements – as a social organism, a social system, an aggregation of individual social actions, or an aggregation of social institutions. Following from this social change is seen as processes taking place within society. Although Marx argues that class struggle is an important driving force for societal development (Karl Marx and Friedrich Engels, 2002; Karl Marx, 1958) most explanations are related to differentiation, increasing division of labor, processes of rationalization, the changes in the political and economic institutions, changes in demography, or the emergence of new ideas and ideologies. Thus organized, collective violence is rarely seen as a driving force in societal development. Since war, as a social phenomenon, most often takes place between societies/states, warfare has become even less important because most often intersocietal relations play a less important role in a sociological analysis. Moreover, the predominant understanding of society has involved a problematic conceptualization of the state as an entity derived from society. Therefore the state and its activities will always be a reflection of the conflicts and interests dominating in society. The state cannot be conceived as an autonomous actor separated from society pursuing its own (geopolitical) interests. Consequently, a fusion understanding of society and state has led to a neglect of warfare.

As pointed out above in recent years sociology and social theory have become increasingly interested in war. In the following sections a number of issues related to sociology of war will be presented but first we need a clarification of the term 'sociology of war.'

What Is Sociology of War?

A clarification of the term 'sociology of war' requires a look into the two concepts, sociology and war. It is beyond the scope of this article to discuss the concept of sociology in detail. In this context sociology is equal to social theory. Inspired by relational sociology (Norbert Elias, 1978; Pierre Bourdieu, 1977; Christopher Powell and François Dépelteau, 2013; Nick Crossley, 2011; Pierpaolo Donati, 2011; Mustafa Emirbayer, 1997) sociology/social theory is defined as the study of social relations, e.g., face-to-face interaction between a husband and a wife, the relationship between a management team and the employees, and the relationship between states. Following from this, sociology/social theory studies how particular sets of social relations reproduce and change. When particular sets of social relations reproduce over time, they constitute institutions, organizations, and/or actors. Thus a continuous

interaction between states constitutes these states as entities and they become 'real' existing entities. When we are interested in the sociology of war the focus will be the relationship between the units waging war – the units are political orders of all kinds (most often we call them states) but here we will call them survival units (Elias, 1978). The claim is that war is a social practice conducted only by emerging or existing survival units. When workers movement is fighting in the streets against the police, this might be an organized collective violence but not a war. Before we move into a clarification of war we need to specify the key form of social organization in this context – the survival unit.

Survival Units – A Point of Departure for Sociology of War

Human beings are always embedded in social relations and the claim here is that since man erected and walked out of Africa, human beings have been organized in 'survival units.' Survival units are as old as human beings but these are not states in the Weberian sense. A survival unit is a political and social order constituted in relations to other survival units. It can take different forms such as bands, tribes, city-leagues, city-states, or nation-states. Another way to characterize a survival unit is to see it as a process of constantly organizing and reorganizing in order to survive and consequently, with an ability to provide security and material reproduction. According to Elias the world consists of a multiple number of coexisting and competing survival units. A survival unit is always located in a figuration – a set of interdependent relations between several survival units struggling for recognition by other survival units (Elias, 1978). For clarification it is worth mentioning that a figuration can be seen as a variant of a network structure, and some figuration sociologists (Baur and Ernst, 2011) regard figuration analysis as equivalent to modern social network analysis (John Scott, 2000).

So far we have not laid out an argument that determines the difference between human beings and other animals. A struggle for food, shelter, and protection is common to most if not all mammals. Social groups are struggling for recognition (Hegel, 1977, 1991) and honor (Bourdieu, 1977). Social groups of human beings are in this very struggle experiencing stages of being conscious and self-conscious and, consequently, developing an identity. This ability to experience, feel and gain consciousness, self-consciousness, and identity is apparently distinctive human. Identity, in other words, is a human feature, which is as crucial as eating, sleeping, and having a shelter. In our endeavor to achieve identity we have to confront 'the other,' individually as well as a social group. In our daily material life we hunt, gather, grow, and trade food, we build shelter, we make clothes, and during these social practices we struggle and express our identity. Sometimes we have to fight for these material interests and this fight is not merely a fight for material survival. It is also a fight for spiritual and mental survival – in other words, a struggle of identity. Identity is crucial to human beings and it can only be expressed through our social practices and property (Hegel). The key point is that identity can only be achieved by being in a social relation. Identity is dependent upon 'the other.' Someone outside yourself must recognize you. 'The other' is the precondition of identity-making processes. This struggle of identity is in the last instance a life-and-death struggle – which under certain circumstances can lead to war. This conflictual relationship is the center of concern for sociology of war.

Elias argues that these survival units knit "people together for common purposes – the common defense of their lives, the survival of their group in the face of attacks by other groups and, for a variety of reasons, attacks in common on other groups." He continues:

> Thus the primary function of such an alliance is either physically to wipe out other people or to protect its own members from being physically wiped out. Since the potential of such units for attack is inseparable from their potential for defense, they may be called 'attack-and-defence units' or 'survival units'. At the present stage of social development they take the form of nation-states. In the future they may be amalgamations of several former nation-states. In the past they were represented by city-states or the inhabitants of a stronghold. Size and structure vary: the function remains the same. At every stage of development, wherever people have been bound and integrated into units for attack and defense, this bond has been stressed above all others.
> (Elias, 1978: pp. 138–139)

The relationship between survival units (or states) is a confrontation, which generates identities and boundaries. A state becomes a state when it is in a social relationship with another state. It is exactly in the very moment when two or more states are interacting that they constitute each other as states (Hegel, 1991: pp. 359–371).

Hegel explains exactly that the concept of state is unthinkable unless we see a state as a part of a social relationship – vis-à-vis another state. Similarly to an individual who cannot become self-conscious and know that 'I' is me before 'another' has recognized me – 'I' – from the outside, Hegel clearly sees that a state can only become a state with a bounded territory when the boundaries of this territory are drawn from outside. Elias follows a similar kind of relational thinking by stressing the importance of the very relationship for the 'entities' – the survival units. In this very relationship, boundaries are created from 'outside.' The survival units are demarcated by other survival units and not just by the members of the survival unit itself. Their very relationship constitutes states.

Survival units also take on the role as the 'primary' figuration because of their high degree of autonomy, which no other figurations have. Of course, these figurations are also interdependent with other figurations but they have autonomy to the extent they can "fulfil effectively for their members their function as self-reliant and self-regulating defence and survival units" (Elias, 1974: p. xxii). Their high level of autonomy consists in their ability to defend and survive. As long as a unit can defend its own domain of sovereignty (whether this is territory, hunting fields, seaways, or something else), it can be argued that it has the largest possible form of autonomy. If no other unit can encroach upon your domain of sovereignty you can uphold a political order and you are as autonomous as you can be. This is a crucial difference between survival units and other figurations such as families, cities, or companies. Families or companies can very rarely protect themselves from internal and external enemies.

As long as the survival unit is capable of preventing external enemies from encroaching upon its domain of sovereignty, there will be some degree of freedom and autonomy for families, individuals, and businesses.

In looking at the key role of survival units, Elias also emphasizes the problem of violence. He argues that the violent aspect of the survival unit is in the last instance the key dimension of the state/survival unit (1987a: pp. 74–86). In a discussion of the cold war dynamic between the two superpowers, the USA and the former USSR, Elias emphasizes how this social dynamic creates competitive pressures, which continually change and move these states. Their violent potential is the key means to maintain and improve the position of a state in a system of states.

This interstate dynamic is a life-and-death struggle, which consists of the use or threat of the means of violence. There are many different forms of survival units, which are all interdependent because they are competing with each other in a struggle for survival. It is a contest without rules but it is not chaotic. The struggle between survival units is 'a primal contest.' Two survival units struggle for survival – whether it is about prestige, scarce resources, or other things – they are dependent on each other. Each and every step taken by each of the two parties is watched by the other. As enemies they perform a function for each other and each move of one survival unit determines each move of the other survival unit and vice versa (Elias, 1978: pp. 76–80).

This interdependence exists as a precondition for and influences the character and nature of the internal structure of survival units. In modern terms, the organization and structure of society is to a large extent determined by the intensity of the struggle between states. The character and organization of internal social structures is a function of external structures. Their function for each other is in the last resort based on the compulsion they exert over each other because of their interdependence. It is not possible to explain the actions, plans, and aims of either of the two groups if they are conceptualized as the freely chosen decisions, plans, and aims of each group considered on its own, independently of the other group. They can be explained only if one takes into account the compelling force that groups exert upon each other and their bilateral function for each other as enemies (Elias, 1978: p. 77).

The crucial difference between interstate and intrastate relations is the presence and the restrained use of the means of violence. Elias draws upon Max Weber (1864–1920) in his understanding of the survival unit by arguing that the use of violence is an ever-present threat and the normal instrument of last resort in interstate relations. The use of physical violence has almost been eliminated from normal relations within developed states. This is not only indicative of the fundamental difference between the structure of human relationships within states, but also of that of the relationships between states. This significantly means that human beings live simultaneously at two levels whose structure is not only different, but in some respects contradictory. At one level it is strictly forbidden to be violent and to kill people; at another, it is demanded as a duty to prepare for, and to use, violence in relations with other humans (Elias, 1987a: p. 80).

Elias points out that there is a clear difference between, on the one hand, figurations called states or survival units that are interrelated in a state system and, on the other hand, figurations found at the intrastate level such as families, companies, and voluntary associations. The existence of monopolies of the means of violence within states and the nonexistence of such monopolies at the interstate level can clearly explain differences in social structure. A given state-society – a network of functionally interdependent human beings – has a structure of its own. They are bound to each other in specific figurations whose dynamics have a constraining and compelling influence on those who form them.

The existence of a monopoly of physical force within states and its nonexistence in the relationships between states is an example of the firmness of the structure, which interdependent human beings form with one another. It also shows the far-reaching effects, which these structures have on those who form them (Elias, 1987a: p. 79).

We should also be aware that these survival units take on different forms in different periods in history. Over time they have grown in size – from small bands, tribes, city-states, village-states, to modern large-scale states and nation-states.

At this point it should be clear that the survival unit is the center of concern when it comes to war. It is a social and political organization with the capacity to wage war, and the political locus in the survival unit decides on war and peace. Any survival unit deciding on war is situated in a life-and-death struggle to remain or to gain recognition. War, or the threat of war, generates a number of opportunities for changes in the survival unit or the related society. Sociology of war is an attempt to understand the implications of war for survival units – it is about social change related to war!

War

This requires a clarification of the concept of war. War existed before recorded history. Almost all survival units have engaged in some form of combat against others. This does not mean that war is 'natural,' whatever that means. It is not reducible to an instinct for aggression; even if such a well-articulated instinct did exist, there are plenty of other avenues for its expression (Hirst, 2005: p. 51). As Carl Von Clausewitz (1780–1831) says: "War is the continuation of policy by other means." War is the organized pursuit of interest, it involves violence but it is never just a fight between angry people. War is a conduct. It is something that arises in and through structured human interaction. War happens when social groups categorize others as 'enemies' and take organized action against them involving force. A relation of enmity is one in which, as Hobbes says, the will to give battle is known. Fighting may be episodic, but the possibility of conflict is constant (Hirst, 2005: p. 51).

Enmity exists because of a conflict of interest between groups in relation to a mutual process of recognition that cannot be resolved except by combat, in which one group attempts to prevail in some way over the other. "The interests that group people into friends and enemies are various: they can be material or symbolic, groups fight over resources, but they also fight over principles, beliefs, wrongs done to them, or as a means of defining the individual status honour of warriors or of establishing groups prestige" (Hirst, 2005: p. 51).

At its simplest, war consists of combats. Clausewitz starts off with the analogy of two wrestlers each of whom attempts to force the other to submit. From this simple initial definition he is able to construct a complex and comprehensive theory of war. His core definition is: "War, therefore, is an act of violence intended to compel an opponent to fulfill our will." Such acts of violence are not rule-governed, war is not a game. It is complex but unregulated reciprocal action. Each participant in the combat must anticipate and respond to the actions of the other. Hence, war is inherently uncertain, combat cannot be planned. Because war involves two sides each composed of individuals who must cooperate and coordinate, because it takes place in a context of space and time that cannot be given, because it involves a changing physical environment, it is subject to those forms of uncertainty and chance that Clausewitz calls 'friction.' To overcome the enemy and to counter friction, fighters must be resourceful, act together, and have high morale. Other things being equal, it is morale, the will to win and to accept suffering and effort in order to do so, that ultimately decides the outcome. Given forces of equivalent numbers and morale, reciprocal action, the logic of blow and counterblow, means that there is an inherent tendency in war to ascend to extremes, to ever-greater violence, the ultimate state of which Clausewitz calls 'absolute war.' This state of absolute war is never attained precisely because of friction (Hirst, 2005: p. 52).

It is important to make it clear that war is a political phenomenon and the purpose of war is politically determined. By making the distinction between purpose and aim, Clausewitz can separate politics and war. Politics is the subject of the theory, which starts the war and provides the purpose of war. War itself, however, has its own aim.

The following theory cannot tell anything about the character of the political will involved. It only emphasizes that war is a means, and thus only an instrument of politics.

The concept of war can be specified in three 'layers': the 'explosive,' the 'virtual,' and the 'limited' (or 'moderate') war. Clausewitz himself operated with a theory containing two forms of war: explosive and moderate war. From Anders Boserup (1940–90), however, we know that a third form can be deduced from Clausewitz's text: 'the virtual war' (Boserup, 1986).

In explosive war, there is complete polarity between the two opponents, since both have the same unambiguous, universal, and diametrically opposed end. This polarity involves a displacement of the purpose of politics in favor of the real end of war: winning a victory/avoiding defeat (ziel replaces zweck). It is a true duel on a large scale (Clausewitz, 1993: p. 83) in which all means can be used. The aim is clear: to disarm our enemy in order to impose our will. This leads to an explosive and unlimited war where hesitation can mean losses and/or defeat. This state of war is rarely to be found in the real world, but it still throws light on central features of war.

The next form is a modification of explosive war, called virtual war. Although explosive war takes place now and then, it does not happen very often. Consequently, Clausewitz needed a concept, which could explain the fact that there often is a standstill in war. He needed a concept to explain why the polarity between the two opponents breaks down. If explosive war had dominated history, it would follow that a war would never stop before one of the two opponents had been completely defeated by the other opponent because of a complete polarity – you either win or lose. As we know, this is rarely the case. Clausewitz manages to explain the occurrence of pauses in war and the breakdown of polarity between the opponents by introducing two forms of fighting: the offensive and the defensive principles of fighting. The defensive form of warfare is, in principle, always stronger than the offensive war, which explains why wars stop (Clausewitz, 1986[1832]: Chap. 1, book 1: pp. 15–16). Clausewitz points out that the defensive (D) is stronger than the offensive (O) (D > O), but he has no theoretical explanation for it. Here Boserup can be a useful supplement (Boserup, 1986).

Boserup's argument of the superiority of the defensive is rooted in the condition that the offensive only possesses means, which can be freely mobilized ('the army'), whereas the defensive has not only those but also its own purely defensive forces at its disposal. These forces consist of a series of means that are only raised in consequence

> (…) of the progress of the offensive itself and can only be mobilized by this, such as mountains and rivers, the resistance of the civilian population, and the support from those countries that fear the future strength of a victorious attacker.
> (Boserup, 1986: p. 921)

Thus, the defensive has the possibility of strategically combining its bound and freely mobilized forces, whereas the offensive is only capable of operating with freely mobilized forces in its strategy.

The superiority of the defensive is thus the reason why there may be a real pause, and the length of the pause is conditioned by the strength of the defensive. But during this pause

> (…) the war is continued as a virtual war, for the action of war has ceased, it is true, but the war 'goes on' in a particular sense, viz., as an always present possibility that is only not actual for as long as the conditions of the pause are maintained. The pause is only a precarious, temporary balance, conditioned by the forces keeping each other in check, and thus, therefore, even if the war is only 'virtual', it imposes real claims on the two antagonists.
> (Boserup, 1986: p. 915)

Had the defensive not been stronger than the offensive, history would have looked totally different. If the offensive principle of fighting had been strongest, history would have appeared as an uninterrupted state of war that would only have been terminated when the world was united as one global reign.

By developing the concept of virtual war, Boserup emphasizes that the possibility of war is always present but as long as your defense capacity is stronger than the offensive strength of your opponents, war will not be actualized. It will remain 'virtual.'

The limited war is the third form where political motives (zweck) are once again brought into the picture. During the pause, war may

> (…) take on more limited forms where the antagonists only go for small gains that offer themselves, and where both parties may be said, in a certain sense, to be in the defensive!.
> (Boserup, 1986: p. 915)

Clausewitz's concept of the pause opens up for a new understanding of peace. Peace is here understood as a pause based on the superiority of the defensive. It is the inequality of force between the defensive and the offensive that makes a 'peace' possible, during which societal and state units may exist.

The concept of the pause can also be seen in relation to Hegel's struggle of recognition. The pause is the actualization of a mutual recognition between two survival units (alliances). During the pause a genuine mutual recognition can take place and peace occurs, but it is very precarious because the possibility of war is ever present.

It is important to notice that the concept of survival unit in this context is not a set of political and governance institutions only, but a whole and a unity that includes society. It is not, however, a unity constituted of its internal elements.

The German legal and political theorist Carl Schmitt (1888–1985) approves the Hegelian idea that the very struggle between two entities constitutes this relationship and their two identities respectively. Schmitt says that

> (…) the political entity presupposes the real existence of an enemy and therefore coexistence with another political entity. As long as a state exists, there will thus always be in the world more than just one state. A world state which embraces the entire globe and all of humanity cannot exist. The political world is a pluriverse, not a universe. (…) The political entity cannot by its very nature be universal in the sense of embracing all of humanity and the entire world.
> (Schmitt, 1976: p. 53)

However, he takes this point much further when he specifies that the struggle of recognition is mainly a political relation existing partly among states and partly among persons, groups, or movements in civil society within the state territory. Schmitt argues that the differentia specifica of the political is a friend–enemy relation.

The friend–enemy relationship is a mutual struggle of recognition, and in this case it means a relationship dominated by reciprocal action in which "one can be driven by the opponent's moves, if one does not anticipate the competition and drive it instead" (Hirst, 1990: pp. 130–131). It follows that at the most extreme political struggle includes the possibility of war (Schmitt, 1976: pp. 33–37).

Wars follow from enmity. War is the existential negation of the enemy. It is the most extreme consequence of enmity. It does not have to be common, normal, something ideal, or desirable. But it must nevertheless remain a real possibility for as long as the concept of the enemy remains valid (Schmitt, 1976: p. 33).

Politics can lead to war. Schmitt takes us back to Clausewitz, where "war is the continuation of politics by other means." Schmitt, and more distinctly Clausewitz, elucidate the necessity of the means of violence in order to survive as a survival unit. Violence and military means can become the ultima ratio of a survival unit. It is important, however, to make it clear that war is subordinated to politics. Schmitt indicates that the political relationship and the realm of politics determine the purpose (zweck) of war. The political relationship can initiate the war, but the very aim of the war, to achieve victory/avoid defeat, is entirely determined by the logic of war.

Schmitt has demonstrated that the mutual struggle of recognition that constitutes the survival unit is a political relationship, and at the extreme this struggle involves the possibility of war. War is the ultimate struggle of recognition, and the independence and sovereignty of a survival unit can be at stake. The sociology of war presented here emphasizes that a survival unit can never be adequately theoretically understood unless it is situated in a relation with other survival units.

When a survival unit is recognized it is always a preliminary and precarious recognition, and recognition is always at stake. The very struggle always compels the survival unit to provide a defense. Thus the struggle between the survival units makes heavy demands on each survival unit. The survival unit has to produce a strong political will, economic means, and an ideological support from the population. Therefore, the survival unit must possess a society that can provide these means to maintaining a strong defense. Thus the very struggle of recognition and its specific character has a strong impact on the survival unit, the relationship between the structure of the political order and the structure of the society.

Sociology of War: Social Change and Social Reproduction

So far we have outlined sociology of war with a focus on the always potential conflictual relationship between survival units (or emergent survival units) and the consequences of these conflicts (including the preparations for these conflicts) for the internal organization of the survival units. We have discussed the concept of war in order to determine that war is a particular form of organized conduct, which can be applied to 'solve' conflicts. It has also been argued that war is a particular expression of an existential relationship between two survival units/states, which is used – often in the last instance – to preserve sovereignty and remain recognized as an independent political order. Also, it should be clear that war is an instrument for politics, and consequently, war can only be initiated by political agents with decision-making powers, which are located in survival units or emerging survival units. Thus an outcome of the wars in the former Yugoslavia was new survival units/states such as Bosnia, Croatia, and Slovenia (Mann, 2005; Mulaj, 2008; Ramet, 2010). They were not survival units before the wars, but the war turned them into real existing survival units. Following on from this it should be clear that in principle there is no distinctive difference between war and civil war. A civil war is potentially always a war because the opposing wills usually fight for maintaining one survival unit or to provide the possibility for secession in order to create a new survival unit/state.

Sociology of war examines war as a social transformative force. War is a 'state of exception' in which rules, norms, and

values are suspended and/or undermined, and therefore regime change is not unusual and in addition to this other structural changes take place such as new or amended constitutions, new rights and obligations, a new and different state–citizen relationship, the establishment of new core institutions, etc. A potential conflict, an external threat or an actualized war – in other words, virtual wars as well as real wars – can have an effect on the internal structures and create social change.

When a survival unit – in modern terms a state – is confronted with a threat, prepares for a war or takes part in a war, it will go through a number of changes with implications for ideologies, the self-consciousness of state and population, the relationship to the 'other,' and the self-perception of state and society. It stirs up the social and political order and, in particular, the defeating part in a war is often exposed to a more thorough transformation process. Often the defeat leads to new political leaders, maybe even a regime shift. In some cases the victor imposes a new regime on the defeated and at times even a new economic system, e.g., the Eastern European countries after World War II.

Another aspect concerns in the context of war how different political and social fractions and their struggles for power develop within a particular state/survival unit. If oppositional groups seize the power with violent means, we will characterize it as a revolution. An outcome of a war can be a revolution and most major social and political revolutions in world history have taken place in the context of war, e.g., the French Revolution, the Russian Revolution, and the Chinese Revolution (Skocpol, 1979).

A particular tradition within historical sociology and comparative politics examines the relationship between warfare and state-formation processes. There is a tradition often named the bellicose wave within historical sociology going back to Otto Hintze (1861–1940) and Max Weber (1864–1920). The bellicose wave has become institutionalized as a paradigm with scholars such as Charles Tilly (1975, 1992), Michael Mann (1986, 1993), Anthony Giddens (1985), Gianfranco Poggi (1978), Thomas Ertman (1997), Brian Downing (1992), and Norbert Elias (2000). They all emphasize warfare as a driving force for state formation and the increasing state capacity building over time. War compels the states to increase the ability to extract resources, to mobilize manpower, to build fortifications, etc. War provides a necessity of social change. In addition to this some of these scholars claim that an unintended consequence of warfare is the creation of group homogeneity such as patriotism or nationalism. The classical example is how Napoleon's victorious armies generated not only French patriotism and nationalism but nationalism all over Europe, e.g., Prussia.

Among the most well-known and important scholars within this historical sociological tradition addressing these sociology of war issues most directly and comprehensively are Charles Tilly (1929–2008) and Michael Mann (b.1942).

Charles Tilly: Coercion and Capital

Charles Tilly claims that although many other theories in social sciences and humanities contribute with valuable aspects of state formation, most of them are flawed. Tilly here emphasizes two important problems: A widespread tendency to focus on the state and its internal construction without considering the impact of the state–state relation. Another problem is the neglect of the importance of war and war preparations for the structure of the state. Theories in international relations take this into account, but warfare is usually regarded as a result of the individual state actions – not as a consequence of the very relation between the states. These observations are important and very valuable contributions to social theory in general and sociology in particular. This critique provides the backdrop for Tilly's own theoretical framework. Tilly takes his point of departure in the concept of the individual. Men control means of coercion. These men tried to extend the range of people and resources over which they had power. They became conquerors. Conquerors, who managed to exert stable control over the populations in territories and to extract resources, became rulers. Rulers made wars because they now and again faced limits to their rule. War making led to state making. Tilly takes his point of departure in the interdependence and logics between capital and coercion. These two dimensions develop as an interrelated couple. The expansion of coercion is linked to the development of states, whereas capital is linked to cities. He emphasizes coercion and wielders of coercion as the starting point for the process (Tilly, 1992). The state reflects the organization of coercion and capital – at least in its most developed form. When concentration of coercion and accumulation merge, an increasing growth of state power will take place.

What processes push the accumulation and concentration of means of coercion? Tilly is unequivocal in his answer that war involves accumulation and concentration of means of coercion and consequently, state formation. How come war has been en generic aspect of the world history? Because coercion works. "Those who apply substantial force to their fellows get compliance, and from that compliance draw the multiple advantages of money, goods, deference, access to pleasures denied to less powerful people" (Tilly, 1992: p. 70).

In other words, coercion promotes a compliance, which gives access to resources. This logic seems to be a common feature of the European development. A more specific war-provoking logic was present: Everyone (i.e., kings, princes, barons) who controlled means of coercion tried to maintain a 'security area' and a 'buffer zone' to protect the security area. At times they included the buffer zone in the security area, and consequently expanded to maintain a new buffer zone. This logic leads to war and, according to Tilly this logic has been a generic element of the European history since 1990.

Tilly claims that war is the most important activity of the state during most of the history until our time. A general trend has been that the world has seen more wars with higher intensity but fewer wars between great powers. These wars have become even more intensified and cruel.

War has been the most dominant state activity but not the only one. However, the other activities are all connected to warfare. The minimum activities of the state are as follows:

1. State making: The ruler attacks and controls enemies and competitors within the claimed territory. (Here Tilly implicitly accepts that territory is a part of a state definition.)
2. War making: The ruler attacks enemies outside the territory.

3. Protection: Attacking and controlling the enemies of the ruler's allies (inside or outside the territory).
4. Resource extraction: extraction of resources from the population to state making, war making, and protection.

The war initiates a whole range of processes in the state. The state is forced to war making, state making, protection, and extraction, otherwise the war/defense capability weakens and, as a consequence, the sovereignty of the state is at stake.

These state functions generate more functions like adjudication, distribution, and production of goods. A by-product of the war activities is the development of a number of institutions and organizations like courts, legal institutions, financial institutions, tax administration, regional administration, public assemblies, and parliaments. These institutions later became independent forces with their own dynamics in the state and society.

Tilly examines how the forms and structures of the control of the means of coercion changed from a period with small warrior lords and princes and a fragmented sovereignty (my expression) to large territorial domains. This long process bears witness to a development in which the state is strengthened externally by a strong internal pacification.

Increasingly, the state gets control over the means of violence and succeeded in disarming the civilian population and preventing access to weapons. This created a completely new structure of state and society. The perennial threat from private wars, attacks, internal violence, riots, etc., was reduced to a minimum and the state could concentrate on the threat from external enemies.

War drives the state to an extraction of resources. The state developed financial institutions including a tax and revenue administration. Collecting taxes required extended surveillance and control of the population. Therefore, a huge apparatus was necessary. The tax base was nobility, towns, and peasants, and particularly the towns and cities became increasingly more important in time with the development of commerce and the money economy. Here the state could extract many resources.

The evolution of new institutions and organizations usually took place during wartime. After the end of a war, it became very difficult to demolish them and slowly they became permanent. Military organizations, revenue and finance, credit and banking, and legal institutions must all be seen as a direct or indirect effect of the war-making activities of the state.

Michael Mann: War, States, and Power

The British-American sociologist Michael Mann's main thesis is that society is constituted of many overlapping, intersecting sociospatial power networks. Mann provides a theory and history of power relations. We replace society as our primary unit of analysis with power networks. Mann argues that "a general account of societies, their structure, and their history can best be given in terms of the interrelations of the four sources of social power: ideology, economy, military and political (IEMP) relationships" (Mann, 1986: p. 2).

He underlines that these are overlapping networks of social interaction, not levels or dimensions of a single society. They are also organizations, institutional means of attaining human goals (Mann, 1986).

In terms of methodology Mann argues that it is necessary to make a concrete analysis on a sociospatial and organizational level. This involves the problems concerning organization, control, logistics, and communication. "The capacity to organize and control people, materials, and territories, and the development of this capacity throughout history (…) my history of power rests on measuring sociospatial capacity for organization and explaining its development" (Mann, 1986: pp. 2–3).

Mann contributes to sociology of war by bringing in military power. Military power is defined as the social organization of concentrated and lethal violence. 'Concentrated' means mobilized and focused; 'lethal' means deadly (Mann, 2013: p. 2). Military power becomes intertwined with political power in interstate wars. Political power is linked to the state and is defined as the centralized and territorial regulation of social life (Mann, 2013: p. 2). In order to bring war into social theory it requires a reconceptualization of the state. The state wages war – not simply because it is hijacked by the ruling class to fight for its economic interests – but because the state has its own agenda. Consequently, the autonomy of the state is central in Mann's works (Mann, 1984, 1986, 1988, 1990).

Mann's project is an attempt to break with, in particular, the reductionism characterizing liberalistic, Marxist, and functionalist theories, in which the state is reduced to preexisting structures in the civil society. Mann is also drawing upon the legacy from the bellicose thinkers such as Hintze, Weber, Gumplowicz, and Oppenheimer. The state has two dimensions: one has to do with the economic and ideological conditions of civil society and the other with the state's international military conditions. The state responds to two kinds of interests/pressures (both internal and external) generating a particular autonomous 'space' where the state-elite may maneuver and play off the classes against each other.

The origin of autonomous power is related to the necessity of the state. Concerning the necessity of the state, Mann takes his point of departure in a Hobbesian conception of society. The existence of a society is conditioned by the presence of rules that are capable of protecting life and property. These rules originate from a monopoly. Moreover, it is said that states always exist in a system of states, which also imposes certain rules of behavior onto each state. The autonomous power of the state proceeds from this necessity – "necessity is the mother of state power" (Mann, 1984: p. 196).

Only the state has a particular inherent centralized authoritative power over a specific territory. In contrast to economic, ideological, and military groups in civil society, the resources of the state-elite radiate authoritatively outward from a center, which only comes to a halt at a territorially defined border. "The state is, indeed, a place – both a central place and a unified territorial reach" (Mann, 1984: p. 198).

Precisely this property distinguishes the state from other powerful societal groups such as businesses, capital owners, the Church, or the nobility. The autonomous power of the state proceeds precisely from the difference in the organizational structure and sociospatial conditions. "Territorial centralization provides the state with a potentially independent basis of power mobilization being necessary to social development and uniquely in the possession of the state itself" (Mann, 1984: p. 201).

The autonomy of the state therefore consists of its necessity, the plurality of functions and territorial centralization. The power of the state-elite cannot be reduced to the power of any group and it is thus autonomous in relation to civil society.

The development of an active state with great infrastructural power extends territorialization, hereby also the demarcation of society. The development of the European nation-states is used as an example. Two processes in European development contributed to a further degree of centralization and territorialization from the twelfth century onward.

The first condition is the military development, which required more capital (to mercenary soldiers) and later also men skilled in the use of arms (conscripts). Both of these demands could best be fulfilled by territorially centralized states.

The other process concerns the increasingly capitalist economic development. In order to increase growth and wealth, capitalism posed certain requests, which were best met by the territorial states. These states could provide, e.g., military protection against external enemies, a common jurisdiction with legal regulation of property and a guarantee of the currency. Capital was looking for security and conditions of existence provided these states.

Mann, therefore, concludes that the state and its autonomous power is the primary condition of understanding societal development in Europe until today. By his redefinition of the state possessing autonomous power Mann makes it possible to take war and geopolitics seriously. According to Mann the societal development of the world can only be properly understood if we acknowledge that states have their own agenda, in particular, in relation to geopolitics, and thus warfare becomes an important transformative social force in history.

The war (and politics) is regarded as a decisive driving force, and it seems as if war and the struggle for recognition implicitly constitute the state.

Violence and War: Roots and Causes

Obviously, many people ask the question: why do people use violence? Why do states go to war? Since the origin of classical social thought, many attempts to answer questions like these have been made but no clear-cut answer has been provided. Several traditions and theories compete about providing the definitive answer. Thus we find a fierce competition between sociobiological and cultural explanations (Malesevic, 2010: pp. 50–85). Sociobiologists take their point of departure in the assumption that social behavior is rooted in biology and it is an outcome of evolution. In modern versions behavior is related to and determined by certain genetic principles. The core argument is: "human violence is just an extension of animal behavior, which includes aggressive competition over resources or territory with the aim of maximizing one's reproductive success" (Malesevic, 2010: p. 54). Unlike sociobiologists many sociologists and anthropologists stress cultural explanations of violence. War and violence are conceptualized as the product of culture: "while some approaches stress the irreconcilable struggles of different worldviews or theological doctrines as a source of violent action (…), others focus on symbolism, ritualism, and signification as the key features of warfare" (Malesevic, 2010: p. 64).

A competing set of theories emphasizing economic rationality also contributes to an understanding of the roots and causes of war. A simple but strong theoretical perspective can be found in a variety of rational choice models. Rational choice is based upon the assumption that individuals are (purposeful) rational and self-interested. Rational choice theory builds upon the ontology that only individuals and their action exist and social science must take its point of departure in the social actions of individuals. When examining causes of war many rational choice models provide an explanation related to the motivation of the actors involved. War is explained by the economic gains and losses of actors.

Also some of the voices in the globalization debate relate new wars and contemporary violent conflicts to economic globalization processes (Kaldor, 2001; Bauman, 1998). These scholars argue that warfare has become an instrument of economic policy. Thus the war in Iraq in 2003 could be seen as a struggle for material resources.

A central puzzle about war is that wars are costly but nonetheless wars recur. Thus scholars who have studied the origins of wars often have concluded that war can be a rational alternative for leaders who are acting in their states' interest. They find that the expected benefits of war sometimes outweigh the expected costs, however, unfortunate this may be. The two most typical rational choice explanations provided to this question are related to the problem of anarchy or the rational preventive war. The anarchy argument is based upon the anarchical nature of the international system. This is seen as an explanation for the persistence of war. Under anarchy, without a supranational sovereign to make and enforce law, "war occurs because there is nothing to prevent it…. Among states as among men there is no automatic adjustment of interests. In the absence of a supreme authority there is then the constant possibility that conflicts will be settled by force" (Waltz, 1959: p. 188). The argument is related to a fundamental difference between domestic and international politics. Within a well-functioning political order such as a state, organized violence as a strategy is ruled out by the potential reprisals of a central government. In international relations, by contrast, no agency exists that can credibly threaten reprisal for the use of force to settle disputes. The claim is that without such a credible threat, war will sometimes appear the best option for states that have conflicting interests.

The second explanation is related to the notion of preventive war. It is argued that if a declining power expects it might be attacked by a rising power in the future, then a preventive war in the present may be a rational decision.

Conclusion

It is suggested in this article that sociology of war takes as a point of departure that war is a constant in human life and this is an empirical observation. War is a particular conflictual form of social relations when groups (survival units) are struggling for recognition (Lindemann, 2010).

Obviously, we find a great variety of sociobiological explanations of causes of war and the same goes for cultural/sociological and economic explanations. Also theories combining or reconciling the different positions can be found.

This article, however, presents a perspective on the sociology of war, which is not engaged in the question of what causes war.

What triggers a particular war can be accredited to a number of factors, including aggression, demographic changes, economic necessity, or simply misinterpretation of a situation. In other words, a multivariety of causes can create war but it is not possible or within the scope of sociology of war to provide an explanation of the genesis of war and collective violence. It has another advantage, however, because unlike sociology in general this perspective takes war seriously and it provides an explanation for why war stops. This creates a potential for understanding and upholding peace.

Warfare in History

Michael S Neiberg, United States Army War College, Carlisle, PA, USA

Abstract

This article divides the history of warfare into five periods: the Classical Era (including the wars of Persia, Greece, and Rome); the Middle Ages, including the Mongols and samurai (roughly from AD 500 to the Turkish conquest of Byzantium in 1453); the age of gunpowder (from 1453 to the American and French Revolutions beginning in 1776); the 'long nineteenth century' (from 1776 to 1918); and finally the contemporary period (covering World War II, the Cold War, and after). The article considers war in a variety of geographic settings including Europe, East Asia, and the Middle East. Each of these periods will discuss changes in three dimensions. First and most obviously, each period is associated with a general group of military technologies. This article does not argue for technological determinism, but it does review the major changes in military technologies and the ensuing changes technologies have forced on military organization and purposes. Second, each period also involves a shift in the nature of military organization, including leadership, training, and connections to civilian institutions. Finally, this periodization demonstrates changes in the reasons why societies have gone to war.

This article divides the history of warfare into five periods: the Classical Era (including the wars of Greece and Rome); the Middle Ages (roughly from AD 500 to the Turkish conquest of Byzantium in 1453); the age of gunpowder (from 1453 to the American and French Revolutions beginning in 1776); the 'long nineteenth century' (from 1776 to 1918); and finally the contemporary period (covering World War II and the Cold War). Each of these periods will be defined by changes in three dimensions. First and most obviously, each period is associated with a general group of military technologies. Second, each period also involves a shift in the nature of military organization. Finally, this periodization demonstrates changes in the reasons why people have gone to war.

The Classical Period

Technology

The Classical period deserves consideration on its own merits and in the context of a historical debate over the influence of Greco-Roman warfare on later European patterns. In the field of technology, some historians argue that the Greeks and Romans began a pattern of using superior technology to compensate for having to fight wars against numerically superior enemies. The Persian Wars of the fifth-century BC demonstrated the need for Greek city-states to combat the much larger armies of Persian kings Darius and Xerxes. Needing to slow the Persians, Spartan General Leonidas threw his much smaller force into a mountain pass near Thermopylae in 480 BC knowing that it would be destroyed to a man. Aware that his army would not return, Leonidas took with him only those men who had children to succeed them, an important consideration because the army and the citizenry were closely linked.

To avoid future Thermopylaes, the Greeks developed both offensive and defensive technologies. By the end of the period, the typical Greek soldier wore nearly 70 pounds of armor and carried spears and swords that were superior to Persian weapons. These technological solutions helped the Greeks win, but the unity that the Greek city-states showed against Persia soon devolved into internecine wars. During the most famous of these wars, the Peloponnesian War (431–404 BC), technology again proved critical. In this case, Athenian naval vessels attempted to balance the superior land power of their enemy, Sparta. Defensive technologies evolved in counterpoint as Athens, Syracuse, and other city-states built protective walls strong enough to defy even determined sieges.

The Romans also leaned heavily on technology to defeat more numerous enemies, though many Roman military technologies were not necessarily weapon systems. Building upon the Roman genius for engineering, Roman armies assisted in the construction of a system of roads (even today the Roman roads are roughly contiguous with the European highway system) that permitted the legions to move quickly from one point in the empire to another. The Romans also depended upon defensive works such as trenches and walls (Hadrian's Wall in the UK is the most famous example) to contain their enemies rather than fight them. Some historians argue that the Classical tradition bequeathed to later Western militaries the importance of looking for technological solutions to military problems.

Organization

The Greeks based their military upon the hoplite system. Hoplites (named for their shield, the hoplon) were citizens of the republic and rough social equals. Thus, Greek warfare had no concept directly analogous to the modern division of officers and enlisted men. Greek commanders received their appointment by yearly election. Municipal assemblies also voted on when and where the city-state would go to war. As citizens, hoplites participated fully in these elections.

As nonprofessionals, the hoplites needed a fairly simple tactical system because so little time could be devoted to formal training. The result was a dense concentration called a phalanx. A hoplite's shield protected his own left side and his neighbor's right side. Thus the phalanx could only succeed when every hoplite stood his ground, lest the gap between himself and his neighbor be exploited. Once broken apart, a phalanx soon dissolved, resulting in many casualties by trampling.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.96033-1

The Romans trained and organized much more formally than the Greeks. Groups of about 120 men formed 'maniples,' 35 of which were then used to form legions of approximately 4000 infantry and 300 cavalry (the exact sizes of maniples and legions varied significantly over time). This system foreshadowed the modern creation of platoons, companies, and brigades. The Romans used professional gladiators (named for their short, thrusting sword, the gladius) and evolved a concept of officers and 'other ranks.' Increased sophistication and professional training allowed the Romans to develop a military that used various weapons, including soft iron javelins called pila. The soft iron bent on impact so that enemies could not throw them back. If victorious, however, Roman smiths could recover the pila after the battle and reshape them. The Roman system gave the legions flexibility, endurance, and striking power that few militaries could match.

The Greek and Roman systems of warfare mirrored their societies. Both preferred service by citizens, perhaps another legacy to modern nation-states. The Roman system extended citizenship to conquered people, but the effectiveness of its army noticeably declined as more non-Roman militia entered the Roman military. The citizen model was less prevalent in the armies of autocrats such as Alexander the Great. The Romans also gradually separated wealth from military service by introducing regular pay and even retirement benefits.

Purposes

Among the legacies left by the Greeks and Romans to later styles of warfare is the concept of pitched battle. The Greeks especially tended to favor violent, but short, battles intended to solve disputes in a single afternoon. The bloody nature of Greek warfare appalled many of their opponents, including the Persians, who disliked a style of warfare that left even the winners with high casualties. Despite its violence, Greek warfare did follow certain understood rules, including safe passage for heralds and ambassadors and amnesty for temples and other religious sites.

Roman warfare followed a similar pattern. Wars were generally fought with the single goal of annihilating the enemy. The Roman sack of Carthage in 146 BC is the most famous, but hardly the only example. Roman armies typically pursued retreating enemies with cavalry and often treated prisoners severely. In one case, Julius Caesar kept an opposing general on display in Rome for 6 years before executing him. The Roman preference for fast, deadly, decisive battles differed significantly from other cultures. The Aztecs, for example, believed that the purpose of warfare was to capture prisoners for later sacrifice.

The Middle Ages

Technology

The most important Medieval technology was not a weapon, but the stirrup, which inverted the traditional relationship between cavalry and infantry. With stirrups allowing riders to grasp lances and shields firmly and with newer, more durable horseshoes allowing horses to run faster and farther, cavalry came to the forefront for most of this period. The Mongols proved to be the most successful of the horse-based military systems of the Asian steppes; by the late thirteenth century they controlled an empire that stretched from China to modern-day Ukraine. Their military relied almost exclusively on cavalry.

In Western Europe, cavalry proved to be no less important. For the aristocrats who could afford the extensive support systems that accompanied cavalry, horses meant power. The European aristocracy, as well as its Japanese counterpart, depended upon horses, armor, and swords for offensive power and increasingly larger castles for defensive power. The victory of mounted Norman knights over Anglo-Saxon infantry at the Battle of Hastings in 1066 underscored the value of cavalry. The Catholic Church even tried to ban weapons such as the crossbow that threatened the knight's status, though the church permitted the use of such weapons on infidels.

Technological changes also helped to end the period of dominance by the mounted knight. The Hundred Years War marks an important turning point. At the battles of Crécy (1346), Poitiers (1356), and Agincourt (1415), skilled English archers devastated French knights with the Welsh longbow, a weapon capable of rapidly delivering arrows powerful enough to penetrate armor at ranges up to 400 yards. Lacking effective missile weapons themselves, the French knights suffered terribly. At Crécy, the longbows allowed the English to defeat a French force three times its size, further underscoring the Western pattern of looking to technology to compensate for smaller numbers.

Organization

Military training and military service was concentrated in a relatively small group of wealthy aristocrats. In most Eurasian systems, peasants and serfs were not expected to engage in actual fighting, though they might participate in ancillary operations, particularly as archers or pikemen supporting the cavalry. The challenge to kings and other rulers, then, was to maintain the loyalty and fealty of their aristocratic vassals. In the Third Crusade (1189–92), for example, Frederick I of Germany, Philip II of France, and Richard I of England spent considerable time keeping their unruly knights and barons in check. Powerful, aristocratic military orders, relatively independent of royal authority such as the Knights Templars and the Teutonic Knights emerged from the Crusades as well.

In Japan a similar system developed, though loyalty was ordinarily based more on personal than contractual allegiances. The Japanese samurai class emerged in the twelfth century, replacing the conscript armies that had existed previously. The samurai also came to dominate Japanese politics, supplanting the traditional Japanese aristocracy. The failure of Mongol invasions of Japan in 1274 and 1281 removed any serious outside threat to the home islands, leaving the small samurai class in near-complete charge of military affairs. Civil wars and power struggles did occur, but they rarely drew Japanese peasants into the fighting.

In the Islamic world, the Abbasid Caliphate began in the ninth century to use slave soldiers called mamluks. Originally from the steppes of Asia Minor, the mamluks soon translated their military dominance into political dominance in Egypt and elsewhere in the Middle East. They were the only major Islamic force that proved capable of resisting the Mongols, defeating them in 1260 at the Battle of Ain Jalut in modern-day

Israel. The mamluks, the samurai, the Mongols, and the European aristocracy, though different in many ways, shared a near-monopoly over military force in their societies, which were arranged in feudal, or at least fief-based, political systems. All of these systems were prone to succession crises and internal strife. None proved to be militarily superior to any other.

Purposes

Generally speaking, the motivations and purposes for warfare in this period were either religious, feudal, or both. The Islamic empires acquired tremendous territory, in part through military conquest, without significant technological advantages over their opponents. They did so by wedding religious ideology to their military forces. Under the reigns of Caliphs Umar (634–644) and Uthman (644–656), Muslim armies conquered Spain, North Africa, Persia, and the Indus River valley. Their fleets conquered Cyprus and raided Sicily and Rhodes. Qur'ans accompanied Muslim armies, converting men in the regions they conquered.

The Crusades (1095–1291) also reflect a religious basis for warfare in this period. In the eleventh century, the success of the Seljuk Turks against the Byzantines led Pope Urban II to call the First Crusade (1095–99) to defend Christianity against the incursions of Islam. The Crusades reflect the interplay of religion and feudal obligation. The Pope acted both as a religious leader and (more controversially) as a noble in his own right. The First Crusade demonstrated that only knights could be relied upon to form the center of Christian armies. Peasant armies were too large to feed and too unsophisticated to stand up in battle. Of the 30 000 nonnobles who fought in the First Crusade, 25 000 died. Sending young nobles off to the Middle East also served a political purpose for the Pope, removing warriors and weapons from the constant internal struggles of feudal Europe. Thus by the fifteenth century similar and roughly coequal military systems existed in Western Europe, the Islamic empires, the Asian steppes, and Japan.

The Gunpowder Age

Technology

The Turkish capture of Constantinople in 1453 involved 70 heavy artillery pieces, including a 19-ton piece that fired a 1500-pound projectile more than a mile. The appearance of these weapons was not new. Knowledge of gunpowder had moved from China to the Middle East to Europe. At the Battle of Crécy (1346) the English introduced primitive gunpowder weapons to European warfare. Nevertheless, the dramatic Turkish success at a place Europeans considered sacred marked a watershed in military technology. Ironically, the Islamic empires subsequently proved slower to adopt gunpowder weapons than did their European adversaries. By the end of the eighteenth century, Europeans were the clear masters of gunpowder warfare on land and at sea.

Early small arms, like the arquebus, were clumsy, unreliable, and often more dangerous to the shooter than to his intended victim. Until the widespread adoption of the rifle in the nineteenth century the common command given to musketeers was 'level' rather than 'aim' since one could not expect to hit a specific target at any significant distance. Large artillery was even more dangerous to their users and so large that pieces often had to be cast at the siege site. By the sixteenth century, Europeans had standardized ammunition sizes, developed training systems for musketeers, and invented more reliable firing systems for small arms. These changes made both large and small arms more mobile and effective.

Europeans developed gunpowder weapons more quickly than any other society in this period. The simple availability of raw materials and craftsmen were important prerequisites; men who could cast church bells were in special demand as they could easily cast cannon as well. European nobles also had ample motivation to acquire new weapons for their struggles with other nobles. Finally, the European system proved more amenable to allowing private enterprises to develop and sell new weapons. The mamluks and the samurai showed a particular dislike for guns as they tended to undermine the military monopoly that kept them in power.

Organization

Guns threatened the very existence of a horse-based nobility whose expertise was in swords and lances. The age of the knight, already waning, came to an end. Nonnoble musketeers replaced them. Because small arms were so inefficient when used singly, musketeers had to be arranged in lines and taught to fire and load their weapons in Unison. Armies thus became much larger and more disciplined. Aristocrats who remained in military service became the backbone of an officer class that led armies mostly constituted of peasants.

Holland's Maurice of Orange (1567–1625) and Sweden's Gustavus Adolphus (1594–1632) introduced regular drill and other reforms that eventually led to the classic European linear infantry formation. Initially as many as 10 men deep (later two or three deep) it permitted one line to fire, then move to the back. This system maintained a near-continuous rate of fire, but required intense training (the first drill manuals appeared in 1607) and discipline in order to assure the safe and effective operation of guns. Every officer, furthermore, feared the specter of mutiny. Intense discipline, therefore, characterized most European armies; in many cases, the men feared their officers more than they feared the enemy.

Many European nations also developed powerful sail-based navies in this period. England's Henry VIII, excommunicated from the Catholic Church in 1534, sold Church lands to finance the construction of a fleet. Future monarchs continued to build upon Britain's command of the seas, introducing men-of-war in the seventeenth century that were durable enough to carry large cannon. England's *HMS Victory*, launched in 1759, was built from 2000 oak trees, 27 miles of rope, and four acres of sails. It had 104 guns capable of firing 1100 pounds of iron every 90 s. Sea power became critical to acquiring colonies, protecting merchant marines, and projecting power. Britain dominated the 'Great Age of Sail,' but Portugal, Spain, Holland, France, and others used naval vessels to increase their wealth and status.

Purposes

Three purposes dominated warfare: religion; dynastic ambition; and imperialism. The Thirty Years' War (1618–48)

demonstrated the interplay of the first two. Lutheran–Catholic–Calvinist antagonisms partially explain the bloody nature of the war; Germany proportionately lost more people in the Thirty Years' War than in World War II. Religion, however, did not always determine the allegiances of the participants. Catholic France and Catholic Spain, for example, consistently fought one another for control of Italy and Flanders. Gunpowder weapons also led to a concentration of power as wealthy kings, in command of increasingly larger and more disciplined armies (not to mention artillery able to destroy castles), could compel their restless vassals to accept their rule.

The growth of monarchy meant that warfare often followed the dynastic goals of kings. Louis XIV in France, Peter the Great in Russia, and Frederick the Great in Prussia all used gunpowder-based armies to extend their power inside their kingdoms and enforce their will outside. Often, dynastic wars spilled over into the empires Europeans were in the process of building with those same gunpowder weapons. In the Seven Years' War (1756–63), Britain seized France's Canadian and Indian colonies.

Finally, of course, Europeans translated their gunpowder weapon advantages into overseas empires. In this period, their greatest military advantage over non-Europeans was in areas accessible to their great warships. Navies allowed Europeans to enforce their will along the coastlines of Africa and Asia. On land, guns helped to make the Spanish, French, and British empires in the Americas possible. In Asia, 'gunpowder empires' such as the Ottomans and the Mughals also concentrated political power. Japan, after an initial period of experimentation with guns, effectively banned gunpowder weapons in 1587 because of the threat they posed to samurai dominance.

The Long Nineteenth Century, 1776–1918

Technology

This period, dominated by nationalism and industrialization, marked a tremendous advance in military technologies. Many existing technologies became much more sophisticated. Smoothbore muskets gave way in the nineteenth century to rifles, which have a groove cut in their barrels. Rifling and the conical bullet vastly increased the range and accuracy of small arms fire. After the American Civil War (1861–65) various forms of repeating rifles and machine guns emerged. Artillery also became more deadly. By 1918 the Germans had developed a gun (albeit an inaccurate one) with a range of 80 miles. Naval vessels became more deadly as well. Iron and steel replaced wood as the primary construction material and oil replaced coal as the main fuel. *HMS Dreadnought*, launched in 1906, revolutionized warfare by carrying ten 12-inch guns. *Dreadnought* set off a naval arms race that helped to cause World War I. Winston Churchill noted the importance of Dreadnought-class ships to his nation thus: "the Admiralty asked for six, the Cabinet proposed four, and we compromised on eight."

This period also introduced many new types of weapon systems, including (in rough chronological order) submarines, airplanes, poison gas, and tanks. By the end of this period air forces had developed all major roles for airpower in use today except midair refueling. These technologies brought war directly to civilians as never before. Many important communication technologies such as telegraphs (first used in the Crimean War, 1854–56), railroads, and radio changed the nature of military command and control. Advances in medical technology reduced the number of men who died of wounds and disease.

These technological changes affected Western and Westernized societies (including the USA and, after 1853, Japan) the most. Warfare between them, therefore, reached unprecedented levels of violence. Westernized societies also had tremendous advantages against non-Westernized societies. European imperialists were thus able to use new military technologies to move inland in Africa and Asia. Most visibly, Japan, which Westernized very quickly after 1853, easily defeated China, which did not, in the Sino-Japanese War of 1894–95.

Organization

The most obvious change in the organization of armies and navies in this period was the increasing connection between military service and nationalism. National volunteers and conscripts replaced mercenaries, once common in Europe. Between 1776 and 1783, the American colonies used a militia with both local and national roots to defeat a British army partly dependent upon mercenaries. This contrast partially explains the fame of George Washington's crossing of the Delaware River in 1776: his national army captured 1000 Hessian mercenaries in British service.

The American experience, though, is minor compared to the French Revolution. The logic of the Revolution and the wars that followed implied that national armies must be populated by national soldiers. The *levée en masse* of 1793 established the principle that citizens of all ages, male and female, bore some responsibility for national defense. Napoleon extended this principle and most European armies soon copied the French pattern. Nationalism inspired zeal and a willingness to endure. In 1814 Prussia created the *Landwehr* as a permanent peacetime militia and by the end of the nineteenth century most European nations had introduced national conscription. The militaries of states that were not also nations (Austria–Hungary, the Ottoman Empire) declined as a result.

The two most important military reforms of this period were Napoleon's corps system and the Prussian General Staff. A Napoleonic corps was large enough to operate independently since it contained formations of cavalry, artillery, and infantry that could act in concert. This system, however, depended on capable officers. Napoleon therefore introduced a professional officer corps open to talent in place of the aristocratic one upon which Europe had come to depend. Later in the century, Prussia developed a General Staff system to plan wars. Detailed Prussian planning led to victory in the Wars of German Unification (1864 against Denmark, 1866 against Austria, and 1870–71 against France). These successes led all major Western militaries to copy the general staff idea.

Purposes

Military historians sometimes speak of a continuum between 'limited' and 'total' wars. Because warfare in this period tended to be tied to national goals and national identity, this period represented a general shift toward totality. The Wars of the French Revolution, the American Civil War, and World War I

stand as cases in point. In these wars and others, huge proportions of national income were dedicated to prosecuting wars and fundamental social, political, economic, and cultural patterns were forever altered. The increased suffering (and intentional targeting) of civilians also led to totality.

Advanced technologies also made imperialism (often as an extension of nationalism) cheaper and easier for the Europeans. European militaries moved inland with steam-powered ships and railroads. Machine guns, furthermore, made military contests with natives one-sided. By 1912, the Vickers–Maxim gun could fire 250 rounds per minute. As poet Halaire Belloc noted in a turn-of-the-century (twentieth century) poem, "Whatever happens, we have got/The Maxim Gun, and they have not." Nevertheless, isolated cases such as the Boer Wars (1899–1902) demonstrated that modern weapons in the hands of skilled practitioners could make imperialism extremely bloody and costly. The Boers, white settlers in South Africa of Dutch ancestry, resisted the British with breech-loading guns and smokeless powder. It took the British empire more than two and a half years and almost 500 000 men to subdue less than 90 000 loosely organized Boers. The Boer Wars provided a taste of the changes to come in European military dominance after World War II.

World War I caused 20 000 000 deaths, destroyed four empires, and left in place the conditions for World War II. Only wars fought by national armies could have been so destructive. Warfare in this period combined the productive capacity of industrialization with the inspiration of nationalism. This combination, when matched with the classical legacy for pitched battle, produced a level of carnage that continues to baffle historians today.

The Contemporary Period, 1918–2000

Technology

Although this period has much in common with the previous period, one specific technology divides it from all that had come before. Atomic weapons have changed the very definition of warfare. Some scholars have argued that in the atomic age 'strategy,' as the term was commonly understood before 1945, has no real meaning because atomic weapons do not permit a society to apply a level of force proportionate to desired political ends. In effect, a society only has the military option of obliterating one's enemy and, in the process, taking the risk that a similar fate might befall your own society. Atomic weapons created the post-World War II superpower system that informed not only the Cold War but dozens of regional conflicts as well. The challenge of fighting wars under the nuclear umbrella led to American defeat in Vietnam, Soviet defeat in Afghanistan, and war by proxy as the superpowers tried to fight each other through client states in areas as diverse as Southeast Asia, the Middle East, sub-Saharan Africa, and Latin America.

Of course, more than just atomic weapons are important to this period. World War II saw the development of effective long-range bombers and aircraft carriers, capable of delivering weapons over a greater distance. Radar and sonar provided new technologies to deal with enemy air and submarine attacks. By the end of the war, jet aircraft and rockets were operational, though neither proved decisive. More sophisticated transport planes and landing craft allowed for airborne and amphibious warfare to come into maturity as well.

Since World War II, electronics and computers have revolutionized warfare yet again. Cruise missiles and other 'smart' weapons ideally provide more accurate delivery of weapons and, hopefully, fewer civilian casualties as a result. Satellites, helicopters, sophisticated avionics, networked information systems, and stealth technology once again have provided an upper hand to advanced societies, though the Vietnam and Afghanistan cases prove that a technological advantage is not always enough to ensure victory. Nevertheless, today Western societies still depend upon their technological advantages – much as the ancient Greeks did – to compensate for the smaller numbers of soldiers that they can place on the battlefield.

Organization

Initially, the organization of World War II armies was designed to avoid the totality of World War I. The German *blitzkrieg* system attempted to win 'lightning' victories that would not drain German manpower in the trenches. The Japanese, too, hoped to destroy the American fleet at Pearl Harbor and force the USA into a negotiated settlement. Nevertheless, totality soon emerged as the Axis powers sought to annihilate, not defeat, their enemies. More than ever before, entire societies became mobilized. Women participated directly and indirectly in numbers and ways never before envisioned. The pattern of increasing female participation has continued into the postwar period. The USA armed forces used 35 000 women in the First Persian Gulf War, many of them at or very near the front lines.

The totality of World War II led to the end of Japan and the traditional powers of Europe as independent military actors. The end of European hegemony also meant the virtual end of imperialism. Many militaries resorted to guerrilla warfare to try to defeat more technologically sophisticated enemies. Fighting underneath the technology threshold has proven difficult for more advanced military systems. The Americans had great difficulty with the Vietnamese but few battlefield problems with the Iraqis in 1991 because the latter's military was much more like their own that the former's.

Since the end of the Cold War, the general trend has been to much smaller, but more sophisticated, militaries. Virtually all European states have eliminated or greatly reduced conscription. The USA abandoned conscription during the Cold War (in 1973) partially as a result of Vietnam War protest, but also to acknowledge that sophisticated weapon systems require dedicated professional volunteers to operate them.

Purposes

World War II was a contest of three ideologies: democratic capitalism, fascism, and communism. As a result, armies became deeply politicized. Young German males often left Hitler Youth organizations and entered directly into the Wehrmacht. In the Soviet Union, political commissars served with Soviet military units and had as much decision-making authority as generals. Ideology created what John Dower called a 'war without mercy.' Though he was referring to the

Pacific War between the USA and Japan, the same phrase could be applied equally to the war between Germany and the Soviet Union as well. The Holocaust and the German siege of Stalingrad, among other episodes, show the cost of the war to civilians. The former killed 6 000 000 Jews and other targets of the Nazi state. In the latter, Joseph Stalin refused to order the evacuation of the city even in its most dire moments. In the end, only nine Stalingrad children were reunited with both biological parents.

The Cold War interacted with the general decline of European hegemony to impact regional conflicts. Throughout the Third World, nationalist movements and civil wars became arenas where the superpowers armed clients but, conversely, often went to great lengths to reduce global tensions. In 1956 and 1973, for example, the superpowers brokered truces in the Arab–Israeli wars rather than risk a USA–Soviet confrontation. Regional wars like the Iran–Iraq War (1980–88) also became entangled with the Cold War; the weapons that the superpowers made available lengthened wars that had little relation to the global capitalist–communist struggle.

The end of the Cold War, Israel's 2006 war in Lebanon, the Russian wars in Chechnya, and the American-led wars in Iraq and Afghanistan since 2001 have led some commentators to argue that a new era of warfare is upon us. Led by thinkers like Rupert Smith, they contend that postmodern war will increasingly be fought between states and nonstate actors. They argue that with growing economic interdependence wars between major states is unlikely. Future wars, they contend, will require an entirely new approach to defense and security than that posed by traditional state on state wars. They will be characterized by the decline of the state in a globalized world, increasing involvement of civilians in urban warfare, and the emergence of so-called hybrid threats from groups like Hezbollah or Al Qaeda, which are backed by a state but do not have the standard characteristics of a state. If indeed such thinkers are correct, then we are on the cusp of a new revolution in military affairs.

Abstract

This article tries to reframe the question of the conceptual unity and sociological diversity of interstate war while highlighting patterns and causes. The challenge is indeed to be able to account for transformation and heterogeneity without falling into the trap of an all-encompassing definition that would make all mutations a priori consistent with its premises. This will be done by highlighting how the question of the state, war, and the 'interstate' sheds light on the contemporary patterns of interstate war (first section). It is only subsequently that this article can raise the question of the causal pathways and motivating factors associated with past and present interstate wars (second section).

Two dominant ideas pervade contemporary academia concerning interstate war. On the one hand, it is increasingly popular to proclaim its programmed demise (Mueller, 2004). This would be confirmed by the relatively rare occurrences of such wars since the end of Cold War. On the other hand, many traditional international relations (henceforth IR) scholars continue to analyze interstate wars as a permanent and immutable feature of international politics since the Peloponnesian War.

While these two assertions contend for the ability to foretell the future, they unwillingly lend credence to one another. The permanent reinvention of war between states in spite of the abovementioned irenic predictions seems to vindicate the traditional approach. Conversely, because interstate wars are defined by the latter in an asociological and ahistorical way, usually implicitly modeled on past wars, their approaching end can be proclaimed. As opposed to the abovementioned approaches, we will argue for the heterogeneous nature of the phenomenon and hence for an approach that focuses on transformations and diversity. There are good reasons to make such a move. Three interdependent elements, partially linked to contemporary developments, are worth pointing at.

First, contemporary thinking on interstate wars tends to be trapped in a particular imaginary of these wars, linked to a specific time and place, and usually referring to the 'institutionalized wars' of the European eighteenth century (and preferably here the so-called 'great power wars,' i.e., wars seeing the armed forces of two or more 'great powers' fighting each other directly) or the 'total wars' of the twentieth century (Holsti, 1996). It is consequently difficult to see whether the idea of the end of interstate war derives from what interstate war is explicitly said to be by formal definitions or from what it is implicitly expected to look like.

Secondly, the distinction between interstate war and other types of war is increasingly difficult to draw unequivocally. Many wars have an interstate component, but few if any are 'purely interstate.' This might have been the case since the advent of the modern state to some extent. Arguably, it is however increasingly difficult to disentangle 'interstate' from 'intrastate' wars. Already during the Cold War, many civil wars that erupted in the Third World were inseparable from the opposition between the US and the USSR, thus making the idea of bipolar stability dubious at best. Today, many armed conflicts involve government support to insurgencies in third countries, interlocking conflict systems in which two or more governments fight each other directly and indirectly by supporting each other's domestic insurgencies, governments contending by proxy in the context of civil wars in third countries or in mutually contested territories, secessionist conflicts that are seen as civil wars by some and as interstate wars by others, the role of partially recognized states, etc. This does not only beg the question of the external borders of the concept of interstate war. It also raises the issue of the specificity and historicity of interstate war compared to other forms of war: 'nonstate war,' 'intrastate war' (previously 'civil war'), 'extrastate war' (previously 'extrasystemic war') following the current categories of the Correlates of War (COW) data set.

Thirdly, interstate wars are usually denied as wars by governments preferring to refer them as 'intervention,' 'coercive diplomacy,' or 'use of force.' Moreover, the enemy often is not recognized as a government (rather considered an illegitimate regime) or the relation between the designated enemy and the sovereign state on the territory of which it thrives is intentionally blurred as was the case during the Israeli–Lebanon War of 2006. The contemporary challenge is hence also to emancipate academic language from governmental discourse, while simultaneously recognizing that the latter is part of the social reality that academia tries to pin down.

Against this backdrop, this article tries to reframe the question of the conceptual unity and sociological diversity of interstate war while highlighting patterns and causes. The challenge is indeed to be able to account for transformation and heterogeneity without falling into the trap of an all-encompassing definition that would make all mutations a priori consistent with its premises. This will done by highlighting how the question of the state, war, and the 'interstate' sheds light on the contemporary patterns of interstate war (first section). It is only subsequently that this article can raise the question of the causal pathways and motivating factors associated with past and present interstate wars (second section).

Interstate War: From Concept to Patterns

It is difficult to deal with war, the state, and the 'interstate system' separately in order to construct the category of

interstate war: war as we know and represent it is deeply embedded in the historical sociology of the state and it is difficult to think of latter independently of its ability to raise armies and engage them in war against other 'members' of the 'interstate system.' For the sake of clarity, we will however try to disentangle these dimensions in the three next sections, while simultaneously attempting to show how they interact.

The State at War

The concept of the state is often used in at least three conceptually distinct, but theoretically interlinked ways in relation to war: as an organizational-institutional entity; as a sociohistorical configuration; and as a legal entity. Although the definitions flowing from these three approaches are partly overlapping, they do not do so perfectly. Let us see successively these three approaches to the state.

First, when approached as an institutional-organizational concept, the state is often equated with the government and seen as a more or less unitary actor. We hence say the "state has decided…" when the notion of government would be more precise. When identifying the state with the government, one is in fact positing that the state is an institutionalized web of power relations that, at least in international relations, would function as a compact unit headed by the government and differentiated from society. With regards to war powers, the state is then often seen as a political command structure allowing its government to unilaterally impose its decisions on a bureaucracy and military chain of command while avoiding personal rule and societal interference. Whereas political sociologist J.P. Nettl bought into this narrative in 1968, he simultaneously recognized that one has to think of the state as a conceptual variable with different levels of 'stateness' from country to country in domestic affairs (Nettl, 1968). He however thought states to be exempt from such variability in their external relations. His domestic/ international distinction can however not be taken for granted. Not only can different Western states not be considered as invariants from the point of view of interstate war, but also the spread of the modern state beyond the West after decolonization introduced further variation in its empirical forms. As a result, interstate war has become an even more heterogeneous phenomenon varying with the degree of institutionalization, societal interference, or civil–military relations of its protagonists. Hence, while the state as institution was traditionally seen, in war, to imply the allegiance of the population to the government and the former's exclusion from a participation unmediated by the latter, this supposition is increasingly dubious. It is equally noteworthy that most post-1990 interstate wars between neighbors have involved states often described as 'weak' or 'fragile': the Eritrean–Ethiopian War (1998–2000); the South Sudan–Sudan border war (2012); to a lesser extent the Cenepa War between Ecuador and Peru (1995); the Kargil War between India and Pakistan (1999), etc. This highlights the extent to which contemporary interstate wars often occur between states that do not comply with normative definitions of what they are supposed to be.

Secondly, as a sociohistorical configuration, the state is usually defined, following Weber, as a human community or 'institutional association of rule' the governing staff of which successfully claims a monopoly on legitimate violence on a given territory. In this sense, the criterion of statehood lies in the type of organization of violence and social configuration that the government is seen to uphold. Weber's definition is however flexible: it does not involve a monopoly on violence, but the successful claim (and there can be varying degrees of success) to a monopoly on specifically legitimate violence. However, when the infighting between rival armed groups for the violent control over a territory is endemic, durable, and enjoys varying degrees of support, one probably is beyond the reach of this flexibility. It is hence dubious whether there was a Congolese state in this sociohistorical sense during the Congo War II (1998–2003) during which its government was, among others, fighting at least indirectly against other governments (Rwanda, Uganda, Burundi) through diverse proxies.

In Weberian historical sociology, the state is seen as being relatively pacified domestically and generally war-prone externally: the occurrence of civil violence and the capacity of states to wage interstate war are seen as inversely proportional. Indeed, the advent of the state in this sense is linked to the ability of increasingly centralized and bureaucratized power structures to impose a pacified order inside, thus becoming more capable of waging war outside: wars become, at least potentially (but often also actually), more intense and lethal. Interestingly, however, interstate wars become simultaneously less frequent. There is a long-term decline in the number interstate wars since the beginning of eighteenth century and since 1945 they have disappeared from the relations between Western states. The ambiguity between state formation as a process of domestic pacification and as potentially pushing war toward its extremes, both occurring through the increased centralization and bureaucratization of coercion within the state, indeed affects interstate relations as well. States manage to impose order, not only internally, but also on their relations as well, including a stricter separation between war and peace and a lesser chance of nonmilitarized disputes degenerating into full-scale interstate war (Mueller, 2004: 30). It is therefore only an apparent paradox that many of the contemporary interstate wars, rather than being solely triggered by the increase in the capabilities of their protagonists, are in fact linked to the inability, at least on the part of one of them, to control all sustained organized violence on their territory or emanating from it. The US-led invasion of Afghanistan and the Russia–Georgia War are cases in point.

The post-1945 world sheds light on the sociological-historical definition of the state in interesting ways. On the one hand, the outlawing of war (save in exceptional circumstances) by the UN charter further bureaucratizes interstate warfare by submitting it to rational-legal procedures at domestic and multilateral levels (Rasmussen, 2007). On the other hand, there is an increased integration and internationalization of military affairs within organizations such as NATO and other "international 'conglomerates' of state-power" (Shaw, 2002: 89). This effectively limits the concerned governments' autonomy of decision and ability to wage war on their own. It raises the question whether the member states of these 'conglomerates,' in particular in the West, have not in fact pooled their 'monopolies of violence.' In this sense, there are good reasons to believe that dynamics has linked to the internationalization of military organizations account for the

absence of interstate wars between Western states since 1945 at least as much as economic interdependencies or common identities (from which they are inseparable).

Thirdly, from an international law perspective, the state as a legal entity supposes the combination of an effective legal government, a population and a territory. Interstate war, as generally understood, however, implies war against governmental forces and hence a recognition of government as distinct from recognition of statehood. Consequently, interstate war increasingly is denied in political discourse by denying the quality of governmental forces (often by using the notion of regime) to the enemy. For example, Bush Jr. implied that the US was not at war with the Afghan state in 2001 since it was merely trying to destroy its purportedly illegitimate 'regime,' while fighting alongside president in exile Rabanni of the Northern alliance. A similar argument was used during the NATO war in Libya. Typically, political justifications of such denials would contest the legality and/or effectiveness of what might previously have been seen as the government or what others might see as the government. What is at the crux of the matter is that, as previously seen, the UN charter is understood to have outlawed interstate war (save in exceptional circumstances) and the type of objectives that these wars historically have been associated with: territorial expansion. The resulting negative connotation of interstate war implies that it has to be denied when waged.

As shown by what precedes, the meaning of "interstate war" is not devoid of ambiguities, amongst others because the concept of the state is itself polysemic. It therefore needs to be specified, shall it be used rigorously. We will here approach interstate war as a form of organized violence between governments claiming a monopoly on legitimate violence, usually (but not always) with success, on a given territory. We will use the concept of 'stateness' to account for different levels of institutionalization and monopolization of the state thus defined.

War as Organized Violence

According to Hedley Bull, war is "*organized violence carried on by political units against each other*" (Bull, 1977: 184). War, thus defined, predates the advent of the modern state and not all wars involve states. The central aspect we want to emphasize is the one of organized violence. Indeed, it has at least three dimensions: war involves the organization of practices of physical violence, war entails the organization and institutionalization of reciprocal violence, and in war a specific organization resorts to violence and organizes society for this purpose.

On the first aspect, war involves a collective maintained by a more or less hierarchical structure. This organization constrains a group to stand and fight rather than breaking up, fleeing, or engaging in interpersonal violence. The state involves a high level of functional specialization, bureaucratization, and monopolization of violence, and hence a particularly high organizational capacity to extract resources (manpower, money, etc.) both for its armed forces and for their administration. As a consequence, there is a tendency to implicitly assume that interstate war is the 'purest,' because the most organized, form of war. This representation is questionable, if not for any reason because civil wars can be just as organized and 'conventional' as interstate war as shown by the American or Spanish civil wars. In historical sociology, it is however often assumed, in line with this representation, that following Charles Tilly's often-quoted phrase "*wars made the state, and the state made war*" (Tilly, 1975: 42), which is sometimes wrongly assumed to mean that all wars make states and that all states were created by war. As the description of a process that took place at a specific time and place, this description is certainly correct: the territorial wars of early modern Europe and the "elimination struggles" (Elias, 2000) they entailed, created an impetus for sovereigns to increase the extraction of resources and institutional capacity. The resulting bureaucratization gave rise to increasingly similar states. Here war-making and state-making were dynamically interlinked and these wars hence became more and more 'interstate' in nature.

When taken out of history, simplified and transformed into a universal law, this statement becomes highly problematic: war can destroy states, not all wars build states and not all states were built through war. The state as a sociohistoric configuration, however, as opposed to 'all particular states,' emerged through the wars fought at a specific time and place. In this respect, contemporary interstate wars are very different. When engaging Western troops in overseas military operations, they are too asymmetric and the density of the interactions between the 'units' involved too diffuse for the notion of competitive struggles to make sense. When engaging neighboring countries or regional conflict systems, their mode of financing and resourcing (often external rather than internal), and the prior definition of 'national territories' by the principle of intangibility of international borders transforms the process significantly: states can be significantly weakened without disappearing (contra the above-mentioned idea of "elimination struggles"). Organized interstate violence cannot any longer be seen as the central mechanism through which states are consolidated.

The second aspect concerns the organization of the violent encounter between armed forces. War usually involves some degree of agreement between the opposing military forces on rules, norms, and principles. Because the early interstate wars in Europe involved a high degree of interaction between 'units,' because no state managed to become stronger than all the other states combined and because a similar bureaucratic rationality came to define interstate wars, common rules were emerged. Interstate war became increasingly institutionalized between the seventeenth and nineteenth century as a central institution of what was thought of as a shared interstate system. It is still often through this institution that wars are conceived of. As a more or less coherent, legitimized, and commonly accepted international institution, interstate war however has been eroded as previously seen. As traditionally codified in the law of nations, it has lost its unity.

The third aspect is that governments use violence and organize society for this purpose. In this regard, while the increasingly total wars from the French Revolutionary Wars to the World War II violated many of the rules of the 'institutionalized wars' of the previous period (distinction between civilian and combatants, limited aims, etc.) (Holsti, 1996), they gave a very concrete meaning to the state. Not only did it

involve a territorial monopoly on legitimate violence, but also a total mobilization of the population and the economy. In this respect, the post-1945 period, arguably because of the horrors of the World War II and the invention of the nuclear weapon, has marked a significant shift. The Cold War saw the Western bloc experimenting with the concept of 'limited war,' wars that would remain below the nuclear threshold and avoid drawing in the USSR. The post-Cold War world saw the advent of a more radical idea: that war could be a "*spatially and temporally discrete affair without fundamental ramifications for society and politics in the West*" (Shaw, 2005: 2). Today interstate warfare, as waged by Western states, hence mainly remains a strictly governmental affair, minimizing risks for the Western military, economy, population, and for the government itself. The lesser salience of interstate war in Western societies today is at least partially linked to the fact that it has ceased to organize social life when it occurs.

Interstateness as Reciprocity and Similarity

War in principle involves reciprocal acts and a strategic interaction. In strategic thinking, it is understood to imply a same rationality, a common game. The 'interstate' nature of war potentially adds a further level of reciprocity. In principle, states share a same type of institutional setup and social identity, which historically makes the concepts of rivalry and mutual recognition a central feature of interstate war. In the standard realist and neorealist theory in IR interstate war is accordingly described as occurring between 'like units.' Three questions might be raised in this regard.

First, can the assumption of wars between 'like units' be maintained beyond a certain level of difference in sociological constitution and military capabilities between states? Since states are deemed to be 'like units,' interstate wars are usually defined by contradistinction to asymmetric conflicts: wars between 'units' between which there is a considerable qualitative difference in nature. It is however generally assumed that quantitative differences are transmuted into qualitative ones beyond a certain threshold: if differences in capabilities are overwhelming, the weaker part might cease to act 'conventionally,' as a 'like unit.' From this point of view, it is interesting to note that since 1945 there have been no so-called 'great power wars.' This might be explained by deterrent effect of nuclear weapons and/or by the increased integration of the armed forces of the Western 'great powers.' Consequently, contemporary interstate wars involving so-called 'great powers' have been highly unequal from the point of view of capabilities: the Russia–Georgia War, the Gulf Wars, etc. In the case of the 1999 NATO war against Yugoslavia and the NATO–Libya war the level of asymmetry even implied that there was very little in terms of reciprocal violence. This does not formally make these armed conflict less of interstate wars. It however makes them less different from wars considered as 'extrastate wars.'

Secondly, do the governments have to recognize each other's states as like units? From a social sciences perspective, this question could seem irrelevant. The fact that Egypt and Syria did not recognize Israeli statehood has not prevented the Ramadan War (1973) from being seen as an interstate war. The question is however interesting since a war between a government and a self-proclaimed independent state enjoying *de facto* territorial control might have much in common with an interstate war. It hence raises questions regarding the specificity of interstate war. Moreover, since recognition both implies common rules and spurs rivalry, it is a crucial dimension of the traditional view of interstate wars.

Thirdly, do state authorities have to retain formal control of the combat forces or are proxy wars involving nonstate armed groups also potentially 'interstate' provided these groups are informally controlled (but to what extent?) and supplied by governments? Traditionally, interstate wars are seen as involving the direct confrontation between official armed forces bearing their weapons openly and having distinctive signs. Since 1945 at least, there is however a continuum between so-called 'nonstate wars' and 'intrastate wars' on the one hand, 'interstate' wars on the other hand, with governments fighting each other through nongovernmental proxies, while sometimes simultaneously fighting each other directly through their official security forces. For example, in the case of the Nagorno-Karabakh War (1988–1994) there were government-supported volunteers as well as government forces on both sides. The same can be said of the War of Transnistria (1990–92). Here again the interstate nature of many contemporary wars seems to be a question of degree.

On the whole, it would be useful to think of 'interstateness' when approaching contemporary wars. Indeed, very often it is more a question of degree than of a strict distinction between interstate and other forms of war. Of course, it is widely recognized in social sciences that interstate wars vary with the number of states involved (dyadic, triadic, multiparty, 'complex,' systemic wars, etc.), with the objectives pursued (territorial wars, resource wars, wars of rivalry, etc.), with their purported intensity (limited wars vs total wars)… There has however been a tendency to assume that, in the context of these wars, the state is an invariable unit within an immutable interstate system, an assumption that is increasingly challenged.

Pathways to War: Causality and Interstate War

The preceding elements highlight the problematic nature of some of the assumptions in the IR literature on the 'causes of war.' Many correlational studies rest on the idea that the compilation of huge data sets can uncover transhistorical laws since interstate war, and indeed the state itself, essentially would remain the same throughout space and time. Other more mechanism-based approaches have not avoided the same pitfall. While most academics consider that interstate and intrastate wars are different enough for it to justify distinct data sets and theories, we have tried to show that comparable differences (increasingly) affect interstate wars.

Explanatory Strategies and Interstate War

Beyond the question of definition, the heterogeneity of interstate war raises at least two partially interlinked problems in relation to causality, the one of potentially varying combinations of causal mechanisms, and the one of context-dependency. Both are tackled by Charles Tilly in his later

works on explanatory strategies (Tilly and Goodin, 2006). Tilly highlights that the 'processes' likely to trigger a social outcome, in our case interstate war, are usually the result of multiple 'causal mechanisms' that concatenate in different ways depending on context. He hence calls for explanatory modesty and contextualization rather than law-seeking.

In relation to interstate war, one such crucial causal mechanism is arguably the one that links the state's increased (respectively decreased) monopolization of the means of legitimate violence on a given territory to the strengthening (respectively weakening) of its territorial control and extractive capacity. This first causal mechanism is not directly related to interstate war but might become so when combining with other mechanisms. On the one hand, the increased capacity to monopolize violence on a given territory allows turning violence outwards in a more efficient way, thus temporarily enhancing the opportunities of waging war successfully. One process associated with the occurrence of war will then combine the first mechanism with a second mechanism linked to government rationalization of strategic opportunities. The Franco–Prussian War of 1870 might here offer an example. On the other hand, the loss of the monopoly on the use of legitimate violence, or fear thereof, creates a 'domestic security dilemma': the attempt on the part of the governing staff to protect itself is seen as threatening by its political rivals (and vice versa), resulting in domestic turmoil (Ayoob, 1995). This internal unrest, and the associated loss of governmental control over violence occurring at its borders, can spiral out of control, into interstate conflict. The governing staff might under such conditions of civil strife also use interstate war as a means to crack down on the designated 'domestic enemies,' to consolidate the government's grip on the population and to externalize domestic tensions by blaming external enemies (theory of diversionary wars). The Iran–Iraq War (1980–88) is a case in point. Here we have a very different second 'process' or pathway giving prominence to a third causal mechanism ("civil violence" spiralling out of control, into interstate war). The generic processes of 'monopolization of violence' is hence as such an indeterminate, and yet a crucial, causal mechanism for explaining the onset of war.

Similarly, the effect of the bureaucratization of the state on its rational-legal procedures is likely to impact differently on the onset of interstate war depending on the mechanisms with which it interacts in a given context. On the one hand it lays the foundations for routinized practices that, by submitting increasingly important means to increasingly ambitious ends, build up acceptance of high-cost wars as highlighted by First and Second World Wars. On the other hand, it furthers the proliferation of ends and paves the way for the notion that the means to certain ends are also ends requiring means: this logic underpins the contemporary idea that risks of interstate war for populations and economies have to be managed and, as far as possible, minimized (Rasmussen, 2007). Furthermore, when alliances and international organizations breed transnational bureaucracies and form 'international conglomerates of state-power,' war becomes less likely within the latter (Vasquez, 2009; Shaw, 2001).

This mechanism and process-based account is not a plea for a naïvely speculative approach to causality. Rather, we argue that Tilly here sheds light on the limits of the linear logic of dominant approaches to causality. It offers a methodologically compelling explanation for the fact that in the social world, as highlighted by Hegelian and Marxian dialectical thinking, 'more of the same' can actually mean 'something different.' As a causal mechanism grows stronger, the relevant social context is transformed and the mechanisms with which it is likely to interact changes accordingly.

Causal-Explanatory Approaches to Interstate War in IR

Most of the IR literature on interstate war follows what Tilly described as the law-seeking account of explanation "*subjecting robust empirical generalizations to higher and higher-level generalizations, the most general of all standing as laws*" (Tilly and Goodin, 2006: 12). We must here recognize that the notion of causality is multifarious in this literature (Levy and Thompson, 2010). Different theories look for different types of causes: permissive, necessary, sufficient, underlying, proximate causes etc., Moreover there are different conceptions of what can or need to be explained. It is the latter aspect that we will use to structure this quick and necessarily cursive overview. First, we will deal with the theories explaining the permanent recurrence of interstate war. Secondly, we will present the explanatory accounts interested in the varying frequency of interstate wars throughout history. Thirdly, we tackle the attempts to shed light on the most likely causes of the wars that do occur. We will here focus on causal-explanatory theories, leaving more interpretivist-comprehensive approaches for the last section. We will disregard theories emphasizing 'human nature' or individual psychology, as this would engage us in a wider debate on the causes of violence and aggression in general, and we equally disregard theoretical explanation of particular wars.

First, many theories try to explain why interstate war is a recurrent feature of interstate relations. This is the case of the security dilemma that, as systematized by Waltz (Waltz, 1979), lies at the heart of so-called neorealist accounts. John Herz first defined the security dilemma as a "*structural notion in which the self-help attempts of states to look after their security needs tend (…) to lead to rising insecurity for others*" (Herz, 1950: 157). In other words, given the structural absence in international relations of any authority able to guarantee the integrity of all states (the presence of 'international anarchy' in the jargon), the defensive measures taken by a government to increase its national security might be interpreted as evidence of aggressive behavior by other governments. Since the latter will most likely take similar measures in response, the first government will ultimately have triggered a process that will not leave it more secure. Security is consequently seen as a zero-sum if not a negative-sum game. While peace might be the preferred option of all governments, they might under these conditions choose their second best option, to attack, rather than to risk the worst-case scenario: to be attacked. The security dilemma hence explains why, tragically, interstate war might always occur, even if all governments prefer peace, this at least as long as international relations are characterized by distrust and defensive measures are seen as threatening. As such, it does not go further in explaining why some wars occur and others do not. There are however great differences between authors considering that the security dilemma can be mitigated (defensive realism) and others who

consider that it is irreducibly acute in all interstate relations (offensive realism).

The 'bargaining model of war,' many of the foundations of which were laid by historian Geoffrey Blainey, similarly tries to explain why war always looms at the horizon of interstate relations. It mainly emphasizes the role of informational disagreements and misperceptions and uses microeconomic methodologies and theories. Rather than focusing on the international structure ('international anarchy'), it typically analyses the dyadic interactions between states. It posits that a government will only attack another provided two conditions are fulfilled: it hopes to achieve a favorable settlement of the underlying conflict (usually linked to scarce resources) that it cannot achieve through peaceful negotiations; given its superior power, it is sure to win the war and to achieve this favorable settlement through war at a lesser cost than what it expects to gain. If however both governments agree on this power asymmetry, the weaker government will agree on this settlement through peaceful negotiations rather than risking a war which it is bound to loose. Wars hence occur when there is disagreement on the relative power balance between states. James D Fearon's main contribution here is to explain, through the rational-choice perspective, why there might be such disagreements (Fearon, 1995). One of the explanations, 'the private information mechanism,' posits that during the peaceful bargaining process, both of the governments have an interest in concealing information about their military capacity to avoid countermeasures by their adversary. In other words, there are rational incentives to misrepresent the relative power balance, which ultimately makes war a recurrent phenomenon in international relations.

Secondly, there are theories mainly trying to explain the changing frequency of war throughout history. Some of these do not focus on the causes of war per se. This is the case of the so-called 'democratic peace theory' according to which democratic states usually do not wage war against one another. This liberal theory however attempts to explain the historic decline in interstate wars, and especially the disappearance of interstate war between Western states, by the progress of democracy throughout the world. While the statistic correlation between formally democratic regimes and the absence of war between them is more or less established (with some exceptions and reservations), there is no consistently validated theory to explain this. It is hence rather highlighting a correlation than causality. Another comparable idea sees economic interdependence as the main reason for the decline in interstate war in Western Europe during the nineteenth century and its absence since 1945. Economic interdependencies would raise the opportunity costs of war and reduce the relative value of territorial conquest. Marxists have however long argued that the opening of markets can actually be an objective of war rather than an unambiguous source of peace. Furthermore, here as well one can wonder whether there is not in fact correlation rather than causality. One could even argue that it is the absence of war that allows for the increase in economic interdependencies rather than the reverse (Shaw, 2001).

Many of the theories of war interested in the varying frequency of interstate war focus on the role played by the distribution of power in the international system. There is here significant disagreement on the question whether international systems based on a symmetric power balance between states (or coalitions) are less likely to witness war as traditional realists and neorealist theories argue, or if systems based on power-preponderance of one state are more stable as some realist-inspired theories suggest (hegemonic war theory, power transition theory, and long-cycle theory). According to the first category of theories (traditional realists and neorealists), governments tend to be risk averse: since a relative power balance implies that no government can be reasonably certain to win a war, they are altogether deterred from initiating war. There is however a debate between them on the comparative impact of multipolarity and bipolarity. Waltz argues that bipolarity will discourage war by reducing the risk of misinterpretation of the power balance (Waltz, 1979). On the contrary traditional realists Hans J. Morgenthau and Edward H. Carr considered that the reverse is true because multipolarity adds to the uncertainty. According to the second category of theorists (power-transition, long-cycle and hegemonic war theorists) power-preponderance is adverse to war: governments are in fact willing to take risks, but only as long as there is a chance of winning which is the case when there is a relative balance. When there is power-preponderance, however, the powerful state has no reason to challenge the status quo and the weaker ones are deterred from doing so.

Thirdly, there are the theories interested in the likely causes of the wars that occur irrespective of historical permanence or varying frequency. This is the case of the multicausal and not strictly rational choice-inspired 'steps-to-war approach' developed by John Vasquez (Vasquez, 2009). He shows that interstate war often is the result of a sequence of events during which the cumulative policy choices made by governments progressively restrain their policy-options during successive interstate disputes. As the crises escalate, they become more likely to spiral out of control. It is what Vasquez calls the 'realist road to war': the mainly nonintentional process though which the practice of realpolitik, as rationalized by the realist theory of IR and the idea of deterrence through 'power balancing,' is likely to escalate. At the same time, Vasquez's approach illustrates some of the downturns of correlational studies: its inability to produce other than commonsensical propositions. The main findings, concerning interstate wars between relative equals, are indeed that: they mostly occur between neighboring states; involve territorial disputes; are preceded by a history of rivalry involving arms races and repeated confrontations; are associated with unbalanced alliances. One of his conclusions is that territoriality, understood as the tendency of humans to occupy and defend territory, is the main underlying cause of interstate war. This view naturalizes a contingent feature of the state. Since states are by definition territorial, and the modern art of war is inseparable from a territorialized view of the world, it is not astonishing that interstate wars often are triggered by territorial disputes. Vasquez is certainly right that the tendency to contend over territory is not necessarily linked to economic interests or expansionist ideologies. This does however not prove, as he implies, that it is linked to the evolutionary past of the human species.

Ultimately, it is astonishing that the literature on the causes of interstate war has taken the state as an abstract given rather than focusing on its characteristics and specificities as a complex organization constituted by its ability to exert

territorial control in violent interaction with other such organizations. The main underlying cause of interstate wars over territory might lie in the territoriality of states rather than of humans.

Understanding Interstate War: Comprehensive Accounts

Collective ideas, ideologies, motivations, and emotions are arguably important factors in the onset of interstate war. The analysis of the latter however supposes to avoid common pitfalls. Rather than being an 'independent variable,' these ideational and emotional factors are simultaneously conditioned and spurred by social and political structures. The tendency to reduce the state to a representative agent with ideas, emotions, and motivations is also one the downsides of the literature on this subject. At the same time, Weber's idea of legitimized violence highlights that the state is inseparable from a long-term, mainly unintentional, shaping of representations, and also, in case of war, of a short-term, more intentional mobilization of "collective will" (Malesevic, 2010). As opposed to a purely causal explanation of interstate war, a complementary comprehensive approach, giving importance to meaning in shaping social action, is then called for.

Some authors have, from a sociological and constructivist-inspired perspective, focused on the role of 'national standing' and the resulting 'struggles for recognition' in triggering war (Lebow, 2010; Lindemann, 2010). They argue that discursively inflated collective identities and the devaluation of the 'collective other' play a significant role in the onset war. These dimensions are important for at least two reasons. First, modern states are inseparable from the historical process of "domestic pacification" (Elias, 2000) and the correlative devaluation of violence. In this respect, the legitimization of collective mass slaughter supposes a prior dehumanization and denigration of the adversary in order to neutralize this principle (Malesevic, 2010). Secondly, states are highly hierarchical and coercive in spite of their principal egalitarianism rooted in formally egalitarian and universalistic mass ideologies (democracy, nationalism, etc.). The resulting contradictions become acute at times of war when some fight and die and some do not. The projection of social hierarchy unto international relations, through a patriotic narrative (often draped in nationalism), hence becomes instrumental to the war effort. It conveys the idea of a homogenous 'national community' to which everybody's personal 'standing' would be linked and that hence temporarily 'invisibilizes' these hierarchies (Lebow, 2010:181; Malesevic, 2010: 272–273). 'Wars for recognition' become then less of a psychological fact, be it on the collective or individual level, than an element deriving from the nature of the state as simultaneously based on structural inequalities and principal egalitarianism.

How far do these theories go in shedding light on a particular pathway to war? One can indeed consider that the factors that they focus upon highlight less of an underlying reason than a permissive condition of war. Moreover, as we have seen, they have themselves structural causes that shed light on their limits as 'independent variables.' However, several arguments can account for the fact that these ideational factors, often conveyed by official discourses and dominant political ideologies, can come to play a significant role in the onset of war: firstly foreign-policy goals can themselves come to be shaped by these narratives and the values and preferences that they convey, thus leading to emotionally charged interstate interactions (reprisals, shows of force…) in which 'standing' is revealed as an essentially zero-sum game; secondly, the domestic social status of the ruling and military elite might be dependent on the ability to claim success in these quests for national recognition; thirdly, to the extent that the resulting narratives successfully mobilize populations and build up expectations, they create domestic pressures on the governing staff to stay true to them and to act accordingly. This might explain the recurrence of rivalries between relative 'equal states' where ideological questions of 'national standing' are particularly salient and where reciprocation of the actions taken by rivals becomes a matter of 'honor' and 'prestige.' Lebow however considers this motivation of interstate war to be in decline due to the normative devaluation of war: if wars of aggression are morally derided, how could they increase 'national standing'? We would however argue that the current Western narrative on civilizational and moral superiority in military operations that are denied as wars, reproduces this logic of 'standing.' Moreover, the normative devaluation of war does not prevent an attacked party from framing this attack, not only as the actualization of a 'material threat,' but also as a 'denial of recognition,' an 'offense,' and to act accordingly (Lindemann, 2010).

Conclusion

Interstate war is variable in time and space. In this regard, this article tries to draw attention to the crucial contribution of, among others, historical sociology to the study of this phenomenon by contextualizing its patterns and causes. It allows accounting for the specificity of the state-form compared to other forms of political organization, but also to highlight the empirical diversity of particular states and 'interstate systems.' As this article attempts to show, such a sociological approach to interstate war also serve to relativize the artificial distinctions that structure so much of the IR literature on interstate war and its causes: between causes located at individual, governmental, and international systemic levels; between materialist and idealist explanations; between the domestic-internal and the international-external realms of the state.

Abstract

This article reviews writings about water with a focus on health from the social and behavioral sciences. In addition, issues related to the equitable distribution of water resources such as potable water and their health consequences are discussed. A case study of one water-related disease (cholera) is used to exemplify the inexorable consequences of the failure to provide clean water and sanitation equitably. The reader also will be introduced to the magic triangle of water, health, and hygiene captured in the Global WASH (water, sanitation, and health) Campaign to include sanitation as a target of the Millennium Development Goals.

Introduction

Throughout human prehistory and history, access to water has been a key concern and often contentious topic. Foraging peoples structure their annual migrations around access to water. Early agriculture that supported the increasingly large and concentrated populations in Mesopotamia was made possible by the construction of complex and massive irrigation canals. These early canal systems were themselves made possible and controlled by the development of a social structure reflecting a specialization of labor. The large-scale manipulation of water occurred conterminously with the growth of large-scale and densely populated settlements and their concurrent evolving cultures. This is but one small example of how water has always been a critical component of human activities from agriculture, industry, urban development, recreation, but most centrally, to life itself. Water has been channeled, dammed, transported, stored in giant reservoirs, dropped from helicopters, sprayed during riots and on forest fires, but most often it is used for the quotidian aspects of life such as cooking, cleaning, and bathing. And access to a clean and reliable supply of water is primary to good health outcomes (Cairncross, 2003; Cairncross and Valdmanis, 2006; Whiteford and Vindrola-Padros, 2011).

While water has long been recognized as a central element in human health, its partner in reducing the spread of potentially deadly diseases, sanitation, has not shared in the same limelight. That is, however, in the process of changing. In 2001, The Global WASH (water, sanitation, and health) Campaign, initiated by The Water Supply and Sanitation Collaborative Council spearheaded a global advocacy movement around safe water, sanitation, and hygiene. In this article, we include the equitable distribution of sanitation, along with water and hygiene, as a critical component to improved global health outcomes.

The recent and deadly epidemic of cholera in Haiti is a classic example of the consequences of failing to provide water and sanitation necessary to maintain the hygiene required to prevent the transmission of fecal/oral diseases. The cholera epidemic following the 2010 earthquake in Haiti demonstrates how water, sanitation, and health are connected and how their presence (or absence) reflects underlying social inequalities. In this article, we discuss the cholera epidemic in Haiti as one example of a devastating water-borne disease. Other water-borne diseases, such as diarrhea, are also killers. As Figure 1 suggests diarrhea, for instance, kills 1.5 million children every year; and is the leading cause of malnutrition in children under 5 years of age (WHO, 2012a). And the tragedy is

Figure 1 Poster created by the WSSCC as part of the WASH Hurry Up! campaign to raise awareness about the current water and sanitation crisis. that both cholera and diarrhea are preventable and treatable. What makes the Haiti cholera example so powerful is that at multiple times, and in multiple ways, it also could have been avoided. It is an exemplar of government failure to create and maintain water and sanitation infrastructure *so* necessary for the well-being of a population. Whether it is cholera in India in the third century, or again from 1817 to 1920 (Watts, 1997), the South American cholera pandemic in the 1990s (Whiteford and Vindrola-Padros, 2011), or the ongoing endemic epidemic of cholera in sub-Saharan Africa (WHO, 2012b), cholera kills needlessly. With clean water and sanitation, the cholera vibrio does not survive to sicken and kill. Clean water and sanitation must therefore be considered universal human rights, as the UN has argued:

> On 28 July 2010, the UN General Assembly recognized that safe and clean drinking water and sanitation are human rights, essential to the full enjoyment of life and all; other human rights. Subsequently, at its 15th session in September 2010, the UN Human Rights Council affirmed that the right to water and sanitation is derived from; the right to an adequate standard of living and inextricably related to the right to the highest attainable standard of physical and mental health, as well as to the right to; life and human dignity. The combined effect of the two resolutions was to anchor the; right to water and sanitation in the framework of the right to an adequate standard of living, making it legally binding like any other of the rights inscribed in UN treaties. Fundamental to the human rights framework is the concept of progressive realization: Governments cannot solve the drinking water and sanitation situation overnight, but; they must make tangible progress towards the realization of this right. Human rights; principles also define various characteristics against which the enjoyment of the right can be assessed, namely: availability, safety, acceptability, accessibility, affordability, participation, non-discrimination and accountability. A distinctive feature of the human rights framework is the principle of non-discrimination. This; requires looking beyond average attainment and disaggregating data sets to determine whether any sort of discrimination is occurring.

Access to a clean and reliable supply of water is neither random nor equitably distributed globally. Geography, history, and politics shape the distribution of water across the globe, and even within countries social groups differ in their access to water (Whiteford and Vindrola-Padros, in press). Hygiene, the practice related to washing one's hands and other body parts to reduce the transmission of fecal-oral diseases like cholera or other forms of diarrhea, is strongly connected to the availability and reliability of a source of clean water (Whiteford, 1999). Social and behavioral science research has repeatedly demonstrated how people's attitudes and practices reflect not only cultural rules and expectations, but also the ability to regularly access clean water (Esrey, 1996). During the 1991 cholera pandemic that moved through South and Central America (in research funded through a bilateral agreement between USAID and the Ecuadorian government), researchers found that in areas of water scarcity, water was used and reused, stored, and parceled out. Clean water was first used in cooking, food preparation, and dishwashing, then for personal use like hand washing or bathing, and then as slops for the animals. As part of the Ecuadorian cholera intervention project, soap was introduced along with health education about the need to use soap. The assessment following the intervention showed many successes, but not in the use of soap (Whiteford, 1999; Whiteford and Laspina, 1996a; Whiteford et al., 1996b; Whiteford and Vindrola-Padros, in press). Ethnographic interviews with women in the households uncovered the reason for the failure to use soap in water that needed to be used multiple times and for multiple purposes. 'The pigs do not like soap in their water' women said, 'so we stopped using soap'. If the pigs were less picky, or if the household had more water so the water did not need to be used so many times, the women would have used soap. The lesson is that in water-scarce settings, householders are particularly conscious of the many uses the water must serve, both inside and outside of the house and adapt their practices accordingly.

Water and Health

According to the World Health Organization (WHO), one of the greatest global challenges to world health is the prevention of water-related disease (WHO, 2012c). Close to 1 billion people lack access to an improved water supply, and there is an estimated 2 million annual deaths attributable to unsafe water, sanitation, and hygiene worldwide. In addition, more than 50 countries report the continuing presence of cholera (WHO, 2012c). Schistosomiasis, another water-related disease, infects an estimated 260 million people globally (WHO). The list of water-related diseases and what parts of the globe people are most affected reflects the continuing inequality of access to clean water and sanitation. An estimated 4% of the global disease burden could be prevented by improving water supply, sanitation, and hygiene (WHO, 2012c). "Poor water quality continues to pose a major threat to human health. Diarrheal disease alone amounts to an estimated 4.1% of the total disability adjusted life years global burden of disease and is responsible for the deaths of 1.8 million people every year (WHO, 2004). It was estimated that 88% of that burden is attributable to unsafe water supply, sanitation, and hygiene and is mostly concentrated on children in developing countries" (WHO, 2012c).

Water-related diseases (some of which can be seen in **Table 1** above) are common worldwide and require environmental as well as infrastructural, educational, and behavior change interventions to control their spread. And as humans continuously modify their surroundings by building canals, transforming wetlands into agricultural areas, removing forests, irrigating arid lands, and by bringing new animals – including humans – into contact with the vectors, the type of threat changes, as do the responses. One classic example of this vector/environment/human health picture can be seen in the story of the Aswan High Dam in Egypt. "In 1971, with the completion of the great dam at Aswan and the filling of Lake Nasser behind it, the epidemiology of Schistosomiasism in Egypt changed radically" (Desowitz, 1987).

Schistosomiasis (also known as bilharzia) is a water-related disease caused by parasitic worms that spend part of their life cycle in the water. More than 200 million people are infected globally and the disease is second only to malaria as the most devastating parasitic disease (CDC, 2012). The parasites that cause schistosomiasis live in types of freshwater snails and the infectious form of the parasite emerges from the

Table 1 Partial listing of water-related diseases and their transmission routes

Transmission/route	*Definition*	*Preventive strategies*	*Examples*
Water borne	Person/animal ingests water with pathogen	1. Improve water quality 2. Prevent casual use of unprotected sources	Cholera; typhoid; infectious hepatitis; diarrhea; dysentery
Water washed	Due to inadequate quantity of water for personal hygiene	1. Increase quantity 2. Improve accessibility 3. Improve reliability 4. Improve hygiene	Cholera; bacillary dysentery; bacterial skin sepsis; scabies; fungal skin infection; typhus; trachoma
Water based	Pathogen that spends part of life cycle in water (all parasitic worms)	1. Reduce need for contact with infected water 2. Control snail pop 3. Reduce contamination of surface water	Schistosomiasis guinea worm
Insect vector	Transmitted by insects breeding or biting in or near water	1. Improve surface water management 2. Destroy breeding sites 3. Reduce need to visit breeding sites 4. Use mosquito bed nets	Malaria, yellow fever, dengue, onchoceriasis

snail, contaminating the surrounding water (see **Figure 2**). People are infected when breaks in their skin come in contact with contaminated freshwater as, for instance, when women wade into contaminated water to wash clothes or engage in other household tasks. The parasites enter the body and become worms that can lodge in the urinary or intestinal tracks and are released back into the water through defecation (CDC, 2012).

In the Egypt case, the Aswan High dam changed patterns of seasonal irrigation and the winter closing of the irrigation canals. Prior to building the dam the schistosome, while endemic to the area was primarily limited to the Delta, and annual relief was provided during the winter season when the canals were allowed to dry out and were dredged to clear them out. As the canals were annually dredged of the accumulated silt, the snails were also removed (Malek, 1975).

But all that changed with the construction of the dam and with the year around activity it made possible. Concomitantly, human activity and fecal pollution (and the distribution of the parasite) increased. As the human population increased, so did its risk of superinfection. Without a doubt the electricity provided by the dam enhanced Egypt's ability to develop the area, but as more than one health advisor has observed: "The beneficiaries of the Aswan project were the snail and the schistosome: they flourish… Unfortunately, the (hydro) electric bill too often contains a high schistosomal surcharge" (Desowitz, 1987).

While the snails may have been a beneficiary of the dam, household and traditional gender roles resulted in women being increasingly exposed to the parasites through increased contact with water contaminated with the snails (Watts, 2004). As the annual dredging of silt (and snail) removal no longer occurred, and as population increased, so did rates of infection, at least in the Delta area. Gender roles and economic status were both implicated in the increased levels of schistosomiasis because certain groups of people (women and people whose livelihoods were attached to the water) were unequally exposed to the contaminated water. This pattern is repeated globally as people in resource scarce countries are more exposed to water-related diseases, and women, poor people, and marginalized or disenfranchised groups are at higher risk of infection.

Gender, economics, geography, and education are all characteristics that correlate to inequalities in access to clean water and sanitation, and thus, are directly tied to increased risk of exposure to water-related disease (Coles and Wallace, 2005; De Alburquerque, 2009; El Katsha and White, 1989; Roark, 2003). Women are particularly vulnerable as they may have to travel considerable distances to bring water from its source to their homes. Likewise, women who must use open defecation practices because of the lack of sanitation often seek secluded areas to protect themselves from being seen. However, that very seclusion may expose women and girls to predatory attacks. These examples show us how water and sanitation are directly tied to power and social inequality (Ahlersa and Zwarteveenb, 2009).

According to a UNICEF and WHO report on the time used to collect water in water-poor areas: "An analysis of data from 25 countries in sub-Saharan Africa, representing 48% of the region's population, reveals that women and girls bear primary responsibility for water collection, at considerable cost in terms of their time. Only a quarter of the population in these countries had water on their premises in 2010, meaning that in 75% of households, water had to be collected from a source some distance from the dwelling. In 71% of all households without water on the premises, women or girls are mainly responsible for water collection. In 29% of households, men or boys assume this task. Further analysis shows that the mean time of one round-trip to collect water is approximately 30 min for both women and men, and is only slightly lower for children (28 min). Each household requires at least one trip per day, but may, in fact, require several trips. The time and energy devoted to water collection is considerable, even based on a one trip per day minimum. In these 25 countries, it is estimated that women spend a combined total of at least 16 million hours each day collecting drinking water; men spend 6 million hours; and children, 4 million hours" (UNICEF and World Health Organization, 2012: p. 31).

One response to the unequal distribution of water and sanitation and their health and well-being consequences is the 1999 Protocol generated by the United Nations Economic Council for Europe (UNECE), The Protocol on Water and Health to the 1992 Convention on the Protection and Use of Transboundary Watercourses and International Lakes (UNECE, 2000).

Article 1 of the Protocol states: "The objective of this Protocol is to promote at all appropriate levels, nationally as well as in transboundary and international contexts, the protection of human health and well-being, both individual and collective, within a framework of sustainable development, through improving water management, including the protection of water ecosystems, and through preventing, controlling and reducing water-related disease" (UNECE, 2000).

According to the document: "… in the European part of the UNECE region alone, an estimated 120 million people, i.e., one person in seven, do not have access to safe drinking water and adequate sanitation, making them vulnerable to water-related diseases, such as cholera, bacillary dysentery, coli infections, viral hepatitis A, and typhoid. Cleaner water and better sanitation could prevent over 30 million cases of water-related disease each year in the region. The 1999 Protocol on Water and Health was negotiated with this in mind.

The main aim of the Protocol is to protect human health and well-being by better water management, including the protection of water ecosystems, and by preventing, controlling, and reducing water-related diseases. The Protocol is the first international agreement of its kind adopted specifically to attain an *adequate supply of safe drinking water and adequate sanitation for everyone* (UNECE, 2000: p. 10, emphasis not in the original) and effectively protect water used as a source of drinking water.

To meet these goals, its parties are required to establish national and local targets for the quality of drinking water and the quality of discharges, as well as for the performance of water supply and wastewater treatment. They are also required to reduce outbreaks and the incidence of water-related diseases.

This Protocol introduces a social component into cooperation on water management. Water resources management should link social and economic development to the protection of natural ecosystems. Moreover, improving the water supply and sanitation is fundamental in breaking the 'vicious cycle of poverty' (UNECE, 2000). The relation between access to clean water and sanitation and good health is clear and has been well understood for decades. However, the global provision of an equitable supply of water and sanitation is elusive. But steps are being taken. Both the Millennium Development Goals (MDGs) and 1999 Protocol provide mechanisms by which to assess and measure improvements in access to clean water and sanitation, and simultaneously (at least the 1999 Protocol) the management of shared resources such as bodies of freshwater. As we will see in the next section, the case of the cholera epidemic in Haiti demonstrates how failed attempts to provide clean water and sanitation allowed the introduction of the cholera vibrio to spread rapidly with deadly results.

Water, Health, and Inequality in Haiti

The 7.0 earthquake that struck Haiti on 12 January 2010 killed 316 000 people and displaced nearly 1.5 million to camps and temporary housing facilities (IOM, 2010). The country was devastated and the large influx of international humanitarian aid was not properly targeted, nor sufficient enough to compensate for the lack of medical resources, destroyed infrastructure, and an ill-functioning water and sanitation system. Internally displaced people (IDPs) were relocated to camps that were not always equipped to handle the large influx of people and many camps did not have water or toilets. The spread of disease was imminent in too many ways.

Since the laboratory confirmation of the first cholera case was made on 21 October 2010 (Mendoza et al., 2011: p. 2177), 250 000 cases, about 125 000 hospitalizations, and 4000 deaths have been reported (Dowell and Braden, 2011; Tuite et al., 2011). The first Haitian cholera case was produced by the contamination of water sources by UN troops who had traveled from Nepal and were stationed near the town of Artibonite (Tuite et al., 2011). Haiti had not experienced cholera for more than a century (Mendoza et al., 2011: p. 1161) and suddenly it had to deal with one of the largest cholera epidemics in the world.

An Epidemic Waiting to Happen

The sharp political, social, and economic inequalities in Haiti set the stage for the rapid spread of the disease, the inability to

contain the bacteria, the late treatment of patients, and the avoidable deaths of thousands of people. As Bell has argued, "problems that occur elsewhere are often more extreme in Haiti, the causes found in the age-old processes of domination and expropriation" (2001: p. 9). Haiti is located in the Greater Antillean Archipelago and shares the Island of Hispaniola with the Dominican Republic. It is divided into 10 departments and Port-au-Prince, the capital, is the largest city (WHO, 2011).

Haitian political administration has been characterized by political instability with 32 coups and a series of brutal dictatorships (WHO, 2011). Pan American Health Organization summarized Haiti's recent socioeconomic situation as follows: "one of the poorest and smallest countries in the world and the least developed in the American region; a high level of corruption and inequality; severe environmental deterioration and deforestation; lack of export industries and a large deficit; an on-going brain drain, primarily to the United States, Canada, and France; most services delivered by NGOs with token supervision and consultation from the Government" (2011: pp. 2–3). With regard to this last point, it is important to highlight the reliance on nongovernmental organizations (NGOs) for the management of the basic services required by the population in Haiti and its negative effect on the role of governmental institutions (Schuller, 2012). International donors and providers of aid have favored foundations and other forms of NGOs when depositing their funds, thus reproducing a privatized form of humanitarian assistance (Schuller, 2012).

Two of the factors most intimately related to the spread of cholera, an inadequate water and sanitation system and poor access to health care, have been severely affected by the political and economic situation outlined before. The public health care system suffered so much deterioration that as of 2010, it delivered only a third of health services (Ivers et al., 2010: p. 2050). Medical care in Haiti has been described as 'an obstacle course, one that places innumerable barriers before poor people seeking care' (Farmer, 1999: p. 145). In 2009, there were three physicians per 10 000 people and 13 hospital beds per 10 000 people (PAHO, 2011). The people who could physically access public services paid for fees as the most basic services had hidden costs (Farmer, 2011). This situation certainly contributed to the low life expectancy (59 for males and 63 for females), high infant (80.3 per 1000) and maternal mortality (523 per 100 000) rates in the country, the highest incidence of tuberculosis in the Americas, and an ongoing HIV epidemic (PAHO, 2011; WHO, 2011).

The water and sanitation system fared no better. Between 2000 and 2004, international aid to the Haitian public sector was significantly reduced, and donors and lending agencies preferred to direct funding to NGOs (Ivers et al., 2010: p. 2048). Water shortage was exacerbated by the earthquake, but it was certainly not a new phenomenon in Haiti. For instance, in 2002, Haiti was ranked last among 147 nations in a water poverty index produced by the World Resources Institute in Washington, DC (Webster, 2011: p. E83). In 2006, it was estimated that only 58% of the population had sustainable access to improved drinking water sources while 19% were able to use improved sanitation (WHO, 2011).

Table 2 The spread of cholera cases in Haiti, 2010

Date	*Event*
14 October 2010	First cholera case in Meille
17 October 2010	First death registered in Mirebalais hospital
18 October 2010	Increase in diarrhea cases reported by the Cuban medical brigades to the Ministry of Public Health and Population
	Haitian investigation team is sent to Meille
19 October 2010	Ten additional cholera cases found in Meille
	The first alert from Bocozel in the Lower Artibonite is received when three children die from diarrhea
20 October 2010	New alerts received from approximately 10 health centers along the lower course of the Artibonite river
21 October 2010	3020 cases, 1766 hospitalizations, and 129 deaths were reported in the Lower Artibonite region
	Epidemiologic confirmation of first case in Meille
22 October 2010	Cholera cases notified in 14 communities in the regions around the Artibonite plain and Port-au-Prince
11 November 2010	Clusters of cases were identified in the North-West Department
14 November 2010	Clusters of cases were identified in the West Department
16 November 2010	Cases confirmed in the Dominican Republic and Florida (U.S.)
21 November 2010	Clusters of cases were identified in the North-East Department (Haiti)

Source: Centers for Disease Control and Prevention (CDC), 2010. Update on cholera-Haiti, Dominican Republic, and Florida, 2010. Morbidity and Mortality Weekly Report 59 (50), 1637–1641; Piarroux, Renaud, Barrais, Robert, Faucher, Benoit, Haus, Rachel, Piarroux, Martine, Gaudart, Jean, Magloire, Roc, Raoult, Didier, 2011. Understanding the cholera epidemic, Haiti. Emerging Infectious Diseases 17 (7), 1161–1168.

In addition, the 2010 earthquake left about 1.5 million people without homes, forcing them to move to temporary settlements, where for many, living conditions worsened (IOM, 2010; PDNA, 2010). In these internally displaced camps, 40% of the camps had drinking water and 30% did not have toilets (Kaussen, 2011: p. 6). As a result of this situation, the cholera bacteria spread at a rapid pace, first in Mirebalais and then in each of the Haitian departments. Trauma victims, those with poor preexisting health status, and nutritionally compromised people could not fight it off and instead became its fatalities. In **Table 2**, we have summarized the different stages of the spread of cholera as outlined by Piarroux et al., 2011, the team of French and Haitian epidemiologists who tracked the dispersion of cholera.

Dealing with the Epidemic

The earthquake that struck the country led to an unprecedented immersion of foreign humanitarian assistance. Foreign assistance took different forms, from the influx of monetary donations to the settlement of medical and assistance personnel in IDPs and Cholera Treatment Centers (CTCs) all over the country. It is estimated that the international community pledged to provide $10 billion in aid to Haiti, but only 2% of

this money had been spent by 2010 (Kaussen, 2011: p. 6). Even though portions of this fund were eventually made available to the country's officials, cases of government corruption were documented, the money was not used effectively, and there was no guarantee that the funds would be used to deal with Haiti's most pressing problems (Farmer, 2011: p. 210).

The coordination of the large number of local and international NGOs working in Haiti after the earthquake and during the cholera epidemic was not without complications. The lack of public oversight of NGOs led to the creation of gaps in services; the distribution of aid was unequal in that a large portion of the aid was focused on the areas that were most affected by the earthquake and not enough attention was paid to the rural areas where the epidemic ultimately emerged; and the overreliance on NGOs for the management of basic services demeaned the role of governmental institutions (Ivers et al., 2010: p. 2048; Schuller, 2010).

By the end of 2011, most public health reports indicated that the cholera epidemic in Haiti had moved toward containment as fewer cases were being reported and treatment was provided to those already suffering from the disease. Several publications, however, cautioned that the improvement of the cholera scenario could be the product of the end of the rainy season in the region and they predicted the disease would probably reemerge once the rain returned (MSF, 2012). That prognosis was also supported by reports that proclaimed that water and sanitation infrastructure had not undergone significant transformations and the living conditions in settlement camps had actually deteriorated (Webster, 2011).

During the first half of 2012, many of these predictions became realities. The rainy season began and the disease continued to spread. Medecins sans Frontieres (MSF) reported in less than 1 month into the rainy season, that the cases of cholera patients in their CTCs nearly tripled. From 16 to 23 April 2012, 134 cholera patients were admitted into MSF's center in Martissant and another 400 patients were admitted to the other MSF centers in Port-au-Prince and Leogane. This organization even had to reopen a CTC in Carrefour to prevent the overburdening of other operating centers in nearby cities (MSF, 2012).

The cholera epidemic in Haiti points to the fact that in areas of the world where water, sanitation, and access to health care cannot be guaranteed for society as a whole, the spread of infectious diseases (like cholera but not limited to it) will remain a latent possibility. The fragile condition of Haitian public services posed a threat to people's lives even before the earthquake struck the country. A natural disaster of this magnitude certainly complicated matters, but Haiti's cholera epidemic was mainly produced by deeper political, economic, and social factors that led to its long-term economic and material impoverishment, dependence on international humanitarian assistance, and lack of coordination of public services.

Social and Behavioral Sciences on Water/Health/Sanitation

The use of water by human populations has been a topic of interest to researchers because of its importance in everyday life. Water is a social commodity in that it 'connects different domains of social life to each other in ways that are not haphazard or accidental because they depend on each other' (Orlove and Caton, 2010: p. 402). In other words, water is not only vital for human existence; it is engrained in all aspects of our society, from gender relations within the household that determine who collects and uses water, to complex economic and political systems that organize distribution at macro levels.

Water has had multiple representations: a quantifiable good that can be commoditized, a scarce resource, a productive tool, and a universal resource (Aiyer, 2007; Derman and Ferguson, 2003). Its connection with all aspects of human life renders water studies varied in approaches; they have focused on the political nature of water, the power relations involved in its control and the inequalities in its distribution (Boelens and Doornbos, 2001; Johnston, 2005). These inequalities are often organized in relation to gender and social class. In relation to gender, "rights and entitlements may shape the ways in which women feel able to participate in particular mechanisms of water access, such as water-point committees or farmers' organizations, how their voices are heard, and how their rights of access are shaped and asserted at the local level" (Cleaver and Hamada, 2010: p. 30). In some societies, gender influences access and use of water in ways that are detrimental to women, excluding them from local property rights and governance bodies, and prohibiting their access to water sources due to religious norms or taboos around menstruation, pregnancy, and childbirth (Cleaver and Hamada, 2010: p. 30). In other cases, women are the ones in charge of the hard labor surrounding water collection, investing energy and time in the collection of a resource that is fundamental for the survival of the household.

The distribution of water is a process involving multiple actors, each with its own needs and interests. Allen et al. have proposed to look at water provision through a 'water supply wheel' (**Figure 3**) where the public, private, and community sectors negotiate different arrangements for water distribution based on policy and needs driven interests. In the developing world, water access is often generated by individual needs and informal mechanisms, rather than by governmental policies, thus leaving specific sectors of the population, usually the resource-poor social classes, without reliable access to potable water (Allen et al., 2006a).

Inequalities in access to safe and potable water have been of particular interest to health researchers as water access, reliability, and quality are strong determinants of health and well-being (Whiteford and Cortez-Lara, 2005; Whiteford and Whiteford, 2005). Systems of water management directly affect the spread of disease and when guided by the principle of water as a commodity, tend to leave marginalized and underprivileged sectors of the population more vulnerable to water-borne, water-based, and water-related infections. Water-borne diseases are caused by ingesting water that is contaminated by human or animal excreta or urine containing pathogenic bacteria or viruses, while water-based diseases are caused by parasites located on intermediate organisms living in water (Montgomery and Eimelech, 2007). These diseases are usually prevalent in areas where people do not have access to running potable water and most frequent other, usually contaminated, sources of water. Water-related diseases are caused by microorganisms with life cycles associated with insects that live or

Figure 3 "Water supply wheel" developed to highlight the different types of water distribution. Source Allen, A., Davila, J.D., Hofmann, P., 2006a. The peri-urban water poor: citizens or consumers? Environment and Urbanization 18 (2), 333–351.

breed in water and water collection and storage diseases are caused by contamination that occurs during or after the collection of water (Montgomery and Eimelech, 2007). When access to water is unreliable, people are forced to store water in containers for future use, thus creating breeding grounds for insects that act as disease vectors.

Sanitation has been a relatively unexplored topic by social scientists (Singer, 2012; Whiteford and Whiteford, 2005). Most studies have stemmed from other disciplines such as environmental engineering and public health (O'Loughlin et al., 2006; Rodgers et al., 2007; Wakeman, 1995; McConville and Mihelcic, 2007). This situation is complicated by the fact that policy discussions on the need to consider access to water as a universal human right do not always explicitly include sanitation (Allen et al., 2006a).

When examining practices of waste management, studies have found that this is an aspect of human behavior heavily influenced by social and cultural factors (Kendall, 2005). The management of human waste is influenced by religious beliefs and ideas regarding purity and danger (Alley, 2002). It is not surprising then that latrine programs that have failed to take these beliefs into consideration have been unsuccessful, such as the latrine program directed by the Swedish Army in Somalia during the 1980s where Muslim refugees refused to defecate facing Mecca (Waldman and Williams, 2001) or proposals for latrine programs in Bolivia where participants would not engage in the digging of their waste because it would be considered disrespectful of the Pachamama (deity of mother Earth) (Aruquipa, 2008).

Where defecation takes place, when, and how are all issues inextricably linked to social categories such as gender, class, and ethnicity (Wakeman, 1995). Previous research found that women and young children are the groups that benefit the most from sanitation programs as they are the ones at greatest risk of violence (attacked in 'defecation zones', victims of rape, etc.) when these facilities are lacking (Schuller, 2010; Wakeman, 1995). The distribution, availability, and quality of latrines and/or toilets mirror the distribution of economic resources in the larger society where disadvantaged groups and the lower social classes are often left without sanitation infrastructure or with subpar services (Allen et al., 2006a,b). In many areas of the world, disadvantaged groups are often indigenous groups because they live in marginalized areas without access to basic services such as potable water and sanitation (Whiteford and Vindrola-Padros, in press). This leads to a higher incidence of water-borne and excreta-borne diseases in particular ethnic groups as evidenced by the cholera epidemics of 1992–93 in the Orinoco Delta of Venezuela (Briggs and Mantini-Briggs, 2003) and 1991–93 in Peru and Ecuador (Whiteford and Vindrola-Padros, in press).

When attempts have been made to change or improve sanitation, these interventions have been influenced by community-level behaviors (Yacoob and Whiteford, 1994) and individual preferences (Kendall, 2005; O'Loughlin et al., 2006; Rodgers et al., 2007). Even in cases where latrine programs have been developed in relation to local customs and practices, many times community members misuse or discontinue latrine use due to bad smell, flies, lack of privacy, or the perception that latrines are dangerous (O'Loughlin et al., 2006; Rodgers et al., 2007). Many studies have, therefore, concluded that technological innovation in the form of transforming sanitation infrastructure needs to be adapted to the local context, in sustainable form, and engaging the participation of community members (McConville and Mihelcic, 2007).

Conclusion

Perhaps no other elements are as central to global health and well-being as water and sanitation. And while the relationship between access to a clean and reliable supply of water and health has long been understood, only recently have people involved in development, and global health begun to include sanitation as the twin urgent need. In this article, we used the case of the cholera epidemic in Haiti to demonstrate how the failure to create an equitable system for a water and sanitation infrastructure resulted in avoidably high levels of loss of life.

Political turmoil over the control of water is perhaps as old as civilization itself. Shaped by power relations and reflected in the inequitable distribution of risk that women, the elderly, children, and the poor suffer from water-related diseases, increasingly attention is now being paid to the combination of water and sanitation. The social and behavioral science research clearly identifies the complex relationships among water, health, and inequality; less clear, however, is how to respond to the complex emergency of increased levels of water-related disease globally.

Practitioners say that global health is sexy – curing people from exotic diseases like Ebola, saving babies and young

children from untimely death due to malnutrition, or providing women with safe childbirth. But sanitation is not sexy. It is dirty, smells foul, and makes people uncomfortable. And yet, everyone engages in it. Some people are forced to defecate in the open; others defecate in streams or rivers or back alleys. At the level of the individual, defecation and other sanitation practices reflect personal, cultural, and religious constraints. At the level of the community, they are questions of political will and infrastructure – and in addition, creating and maintaining a system of waste management are expensive.

The problems that beset improving water, health, and social equality are not, however, intractable. Improvements in water and sanitation are occurring and increasingly occurring with attention to equity. The MDGs, like the 1999 Protocol, have focused attention to the need to rectify the global inequities in levels of health, access to water, and now increasingly, access to sanitation. And, while the future itself may not be clear, the road to improved global health is.

Water Resources and Sustainable Water Management

Jim L Wescoat, Jr., Aga Khan Program for Islamic Architecture, Massachusetts Institute of Technology, Cambridge, MA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Water resources generally focus on freshwaters of the world, which include precipitation falling as rain or snow, infiltrating into soils and groundwater aquifers, running off into stream networks, evaporating from lakes and transpiring from vegetation, and flowing back into the deltas and estuaries along the continental margins. The geographic distribution and flow of freshwaters (analyzed through water-budget studies) affect supplies available for human use, and associated problems of surplus, scarcity, and pollution. Psychological and behavioral research has focused on perception of these escalating water concerns about flood risks, drought hazards, and decision-making, while phenomenological research has explored deeper meanings of water experience. During the twentieth century, social scientific research on water evolved from description of regional water problems (e.g., in the Tennessee Valley Authority); to economic and institutional analyses of water rights, water markets, and the 'range of choice' among water management alternatives; and, more recently, to political and cultural investigations of water and related ecosystem management problems. These developments contributed in the late twentieth century toward ideals of sustainable and integrated water resources management, though those conceptions are now being challenged and refined. Influential debates on social aspects of water have involved Karl Wittfogel's arguments about 'hydraulic civilizations' that drew together the key variables of environmental conditions, water use technologies, economic patterns, property regimes, state organization, social classes, and modes of social power. These ideas stimulated intense theoretical and empirical debates, followed by applied research on sustainable water management in many regions of the world, which argues for continuing attention to comparative international research on water resources, including those of transnational and global scales.

Freshwaters of the World

In the social sciences, water resources research generally focuses on freshwaters of the world. Freshwater includes precipitation that falls over the continents as rain or snow, infiltrates into soils and groundwater aquifers, runs off into stream networks that drain the continents, evaporates from lakes and transpires from vegetation, and ultimately flows back into the deltas and estuaries along the continental margins. This framing of the hydrologic cycle has been central to concepts of sustainable water management, which are woven into the fabric of this article, and it has a fascinating if circumscribed history (Linton, 2010). For example, as coastal and marine resources have involved different types of uses and jurisdictions, they are usually treated separately. However, as populations continue to migrate toward urbanizing coasts, the freshwater–saline interface becomes increasingly important and problematic (e.g., saltwater intrusion, accelerated erosion, coupled runoff–storm surge, and sea level rise). Worldwide, coastal urbanization raises fundamental challenges for water research and sustainability; however, it may be defined. Advances in global environmental science may lead toward greater integration of fresh and saline water research.

Freshwaters constitute only 2.5% of the world's water resources, the bulk of which (96.5%) is in the oceans. The largest proportion of freshwaters is frozen in ice caps and glaciers (68.7%), followed by groundwater (30.1%), lakes (0.26%), the atmosphere (0.04%), marshes (0.03%), rivers (0.006%), and biological water (0.003%) (Shiklomanov, 1993; Trenberth et al., 2007). Biological waters are small in volume but have great social significance because they include the water in human bodies, rapid temporal cycling in plants and animals, and large-scale consumptive use by natural and cultivated vegetation. Research on the history and sociology of water physics and chemistry is questioning how water has been conceived, and in some cases argues for pluralistic water science (Chang, 2012; Linton, 2010).

In addition to their physiological and ecological importance, water resources have been central to fundamental debates about property, power, public interest, the role of the state, and sustainability of socio-hydrologic systems (Sivapalan et al., 2014). Those debates, in turn, have influenced the course of environmental science, technology, and law; and those fields have deepened understanding of the distribution and flows of water from one location, physical state, and quality to another.

Water Distribution and Flows

The static percentages of freshwater mentioned above must be qualified in important ways to understand their social significance. First, freshwaters cycle dynamically in space and time. For example, biological waters are replaced (through ingestion, perspiration, and excretion) on timescales of hours to days, while groundwater is only replaced (through discharge and recharge) on timescales of tens of thousands of years. These temporal cycles have profound implications for human water supply and pollution control. Although biological water needs do not vary much within species, they do vary over organismal life spans, and across geographic regions. The distribution of freshwater also varies by latitude and by climatic processes within latitudinal zones, which range from arid to humid and which vary on seasonal, annual, and longer timescales.

These variations have implications for human water use that are analyzed through water budget analysis (Wescoat, 2013). A water budget compares the amount of water supplied by

precipitation with the amount of water consumed by evaporation and transpiration from vegetation and crops – the largest use of water worldwide. The difference between precipitation and evapotranspiration helps define the magnitude and duration of surplus and scarcity, which societies address by acquiring supplemental water, draining excess waters, or moving to more favorable habitats. Groundwater management requires different approaches and in some regions of the world is so little regulated locally and regionally as to be characterized as 'anarchic' (Shah, 2009). To advance water use accounting, some researchers advocate separating 'blue' surface water from 'green' soil moisture water (Falkenmark and Rockström, 2010).

Freshwaters also vary in physical characteristics, chemical composition, and aquatic life. These characteristics reflect the broad climatic and physiographic contexts that shape the landscape of stream networks, groundwater aquifers, and wetlands. Variations in freshwater distribution, characteristics, and landscapes condition human water experience, which is the primary concern of this article (Gleick, 2012). People who live in snow-covered alpine watersheds have different water supplies, quality, and challenges from those living in temperate or tropical watersheds fed by rain. People living in downstream environments face different water opportunities and problems from those upstream. It is well known that downstream groups face water quantity and quality problems generated by upstream groups, but it is appreciated less widely that downstream groups often have the political and economic power to regulate and constrain upstream development, as in the Nile basin. Many engineering projects of the twentieth century failed to meet their intended goals or gain public support, in large part due to inadequate understanding of such basic social and behavioral aspects of water. Increasingly it is recognized that social research represents an important frontier for water resources management, though it remains underfunded relative to other water sciences (National Research Council, 2004).

Private research funding has addressed some flows, most notably those associated with product supply and value chain analysis. Corporations have found this important for logistics optimization, risk management, and brand protection (World Economic Forum, 2011). Research on virtual water trade has likewise developed from rough estimates of export and import embedded in production and transport to more sophisticated physical and economic modeling (Allan, 2011; Konar et al., 2012).

Psychological and Behavioral Aspects of Water

In addition to supporting life, water has distinctive psychological characteristics. At a physiological level, 'thirst' is experienced differently from 'hunger' and other needs (Ramsay and Booth, 1991). Psychological disorders (e.g., water phobias) include fears of immersion, swimming, and drowning. At a social level, perception of water-related risks and adjustments has received attention in behavioral research on flood and drought hazards, beginning in the 1960s. Flood and drought hazards research evolved from an early emphasis on description of disaster losses and recovery strategies to research that seeks to explain decisions to locate in floodplains (White, 1945; Lamond, 2011; National Research Council, 2000). That research concentrated initially on hazards perception, use of scientific forecasts and uncertainty in decision-making, and the behavioral dynamics of alternative policy interventions – research that continues with increasingly strong connections between theory, experimental research, and practice (e.g., Kunreuther and Roth, 1998; Morss et al., 2005). Droughts develop more slowly than floods and are less commonly addressed in disaster research; they involve different processes of perception, behavior, and adjustment (Wilhite, 2005). Similarly, water-related disease hazards range from vectors in aquatic habitats to inadequate water supply for washing, and vectors that breed in wet areas (Thompson, 2002; White et al., 1972).

Reexamination of pioneering studies of water resources and hazards designed to assess the effects of increased knowledge have noted limited progress in reducing economic losses (White et al., 2001). Efforts to develop general decision-making models to address water problems developed a key analytical construct, known as the 'range of choice,' which attributed failings to undue narrowing of the alternatives considered (Wescoat, 1992; Mitchell, 2008). Criticism of behavioral research on water has focused on structural constraints, especially in developing countries. These criticisms led to research on social vulnerability to water problems. Another small yet important line of phenomenological inquiry questions assumptions about human experience of water (Bachelard, 1983[1942]; Cosgrove and Petts, 1990).

Cultural Representations and Interpretations of Water

Social research on the representations of water (e.g., in texts, arts, and popular culture) is scattered across many fields. In the sphere of belief systems, it includes creation stories such as the *Enuma Elish* that begin with a watery chaos from which fundamental divisions emerge. Comparative studies of flood stories (Dundes, 1988), water deities and rituals, and paradise gardens have continuing significance for many cultures (Blair and Bloom, 2009).

In the modern era, numerous travel accounts proceed from source to sea on major rivers of the world. While tourists generally travel downstream, 'imperial' explorers often labored against the current, searching out navigable trade routes and resources (e.g., Rennell on the Ganges and Lewis and Clark on the Missouri River). Some literary works, such as Henry David Thoreau's *Walden*, influenced contemporary and subsequent views of water. There has been less research on water in the visual arts, music, and film, though that is changing. Ethnographic research on water communities and sustainability issues is increasing dramatically, some of it linking historical and ethnographic research (Mosse and Sivan, 2006; Orlove and Caton, 2010).

Water as an Environmental Resource

Questions about managing water as a natural resource, and about whether 'water is different' from other resources, have been central concerns of social scientists. They are pursued in close association with engineering, natural sciences, and law.

Water management has been dominated by engineering sciences, which have addressed social ideas and problems implicitly if not explicitly from antiquity to the present. Debates on the origin of rivers were resolved with the development of watershed science in seventeenth-century France, which made it possible to estimate water supplies. The expansion of irrigation agriculture also advanced with the development of hydroclimatic water budget analysis. Water pollution control evolved with advances in instruments to measure organic and inorganic contaminants.

This is not to say that traditional water management is unsophisticated, impractical, or ineffective. Humoral theories that originated in Greek and Islamic sciences are still practiced effectively in rural South Asia. Hindu temple tanks and modern irrigation works operate in parallel, though not always in coordination, with one another (Lansing, 1991). The contrast between traditional and modern breaks down at many points. Some traditional irrigation societies devised highly sophisticated water diversion and measurement systems that required elaborate forms of social organization (e.g., *qanats* in Persia). Many modern water systems, by contrast, are supply driven with little measurement or management of water. Irrigation efficiencies in some areas of the western US are only 50%, compared with rates of 90% in Israel and Jordan.

The most acute water problems occur in low-income areas subject to civil unrest, state corruption, weak water institutions, and highly skewed tenure regimes. These conditions have arisen in many irrigation systems and peri-urban areas of developing countries. In such situations, the water institutions that do exist are weakly or inequitably implemented.

Laws define aspects of water that society regards as a resource. From antiquity to the present, legal systems have defined certain aspects of water as natural rights, others as social rights, and still others as *res nullius*. Legal struggles reflect changing social values and water demands. Social research on water laws has focused on four major themes: (1) access rights; (2) water rights transfers; (3) institutional fragmentation; and (4) transboundary conflicts. Research on access rights asks who (including animals) has rights to use water, and what are the social and environmental consequences of different access regimes? Research on water transfers has focused on the impacts of property rights transfers from one type or location of water use to another (Saliba and Bush, 1987). Research on institutions has highlighted fragmentation, gaps, and redundancies among water organizations; and it has more recently begun to focus on power relations among organizations and their social and environmental consequences (Emel and Roberts, 1995). Transboundary conflicts encompass water pollution and floods, as well as water scarcity. During the 1990s, a large body of research focused on transboundary water problems in the Middle East (Committee on Sustainable Water Supplies for the Middle East, 1999).

It is not clear what influence social research has had on water laws to date. The clearest examples involve social research on local irrigation institutions, which have led to the development, testing, and refinement of organizational rules and regulations (e.g., for water users associations; Ostrom, 1992). Social research is sometimes cited in water rights case law or commissioned in interstate and international negotiations, but its effect relative to other considerations is difficult to determine (Delli Priscoli and Wolf, 2009). The slow pace of legal reform has led social scientists to concentrate on public policies where legal issues may be at stake, but decisions will likely be made by water users. One of the oldest policy debates revolves around questions of whether 'water is different' from other resources. Most social scientists grant that water has unique physical qualities and uses but some, principally economists, have argued that water is no different from other resources. By this argument, water is a means to ends that has social values which can and must be compared with those of other resources if society and individuals are to make rational decisions to improve human welfare and environmental quality.

These arguments have stimulated detailed empirical research on the economics of water use. Some researchers have quantified the price elasticity of demand for residential water use while others have focused on agricultural water values (Baumann et al., 1998; Griffin, 2006). These sectoral studies were drawn together in models for optimization and multiobjective management of complex river basins in the 1960s. These models sought to calculate trade-offs among competing water uses for agriculture, flood protection, recreation, municipal, and industrial sectors.

The principal internal debate in these efforts pitted optimization models, based on neoclassical economic principles, against simulation models based on behavioral models of decision-making. After sobering recognition of the limited use of these models, and further technological advances, research in the 1990s began to develop decision support systems. That work built upon research in community-based mapping, human–computer interactions, river basin operations, and adaptive environmental assessment and management. More recently, environmental economists have sought to estimate 'nonuse' values of waters that remain in natural watercourses, the value of 'ecosystem services,' and the trade-offs among competing environmental objectives. However, a growing body of research challenges neoliberal water pricing, privatization, and valuation (Bakker, 2010).

As is evident in the examples above, water resources research has been more concerned with pragmatic inquiry, in the philosophical and colloquial senses of the term, than with metatheoretical debates in the social sciences (Wescoat, 1992). It strives to define the social dimensions of pressing water problems and evaluate the consequences of alternative courses of action. Early research focused on river channel problems (e.g., flooding, navigation, and pollution). The emphasis on channels, rather than basins, reflected legal constraints on the role of federal states in natural resources management. A concurrent line of research sought to describe river basin problems and resources. Basin surveys became increasingly important in the early twentieth century in Europe and the US. The Tennessee Valley Authority (TVA), authorized in 1933, sought to address problems of severe economic poverty, land degradation, and bureaucratic fragmentation. It included regional resource surveys, the design of planned communities, and economic development programs. Although the TVA experiment was not replicated in the US, it had growing significance in postwar development programs in many countries (e.g., the Damodar, Gal Oya, Indus, and Mekong river basins; though see Klingensmith, 2007, for a rigorous historical

critique of diffusion and borrowing). International law has adopted, conservatively and tentatively, the concept of a watercourse system that includes linkages among hydrologic processes, but stopping short of land use, land cover, and basin territories (McCaffrey, 2007).

Policy reforms in the 1930s were influenced by social research on water financing, pricing, and decision-making. The TVA framework was broadened to the scale of national water planning in the 1960s. These efforts culminated in the US with the 'Principles and Standards for Planning Water and Related Land Resources,' which established four evaluation criteria: national economic development, regional economic development, environmental impacts, and other social effects (e.g., community impacts). Economic research focused on the first account, while other social scientists focused on the other three accounts.

One line of opposition to these economic and multi-objective approaches argued that water is different from other resources and that it has unique importance in supporting life. These views were advanced both by water developers arguing for irrigation projects and by their environmentalist and anti-dam opponents. Indigenous values often conflict with all of these arguments and approaches, though oppositions between indigenous and modern values are sometimes presumed rather than studied closely (Boelens and Davila, 1998). Although arguments for the inherent natural or cultural value of water have sometimes been self-serving, they effected a major shift from water development to environmental management in the late twentieth century. In some cases, they have disputed the possibility of commensurating different water uses and values (Espeland, 1998). Policy stalemate is sometimes taken to be evidence of incommensurable values. Analysis of institutional problems, including conflict and stalemate, was a major research advance in the 1970s and 1980s. In earlier decades, water organizations increased in scale and scope to address increasingly complex water problems, but they often weakened local institutions. In response, some research focused on local irrigation organizations (Ostrom, 1992), while others assessed bureaucratic behavior and reform (Coward, 1980). As engineering projects failed to meet their planning objectives and had unanticipated social impacts, increasing attention was directed to 'institutional strengthening,' 'capacity building,' and 'participatory development' (Uphoff, 1992). After two decades of research and experimentation, the importance of institutional factors is well established, though the efficacy of institutional alternatives remains a high research priority.

Beyond these economic and institutional approaches, social scientists have examined an array of specific social impacts in ways that have redefined water resources management. Social research on large reservoirs has focused on displacement and resettlement of people whose homes and lands are flooded by reservoirs, examining issues of equity, state performance, and antidam movements that have stopped international aid for projects in India, Turkey, and China.

Recognition that women, especially in poor rural societies, spend disproportionate amounts of time and energy carrying water and managing domestic water and sanitation led to social research on water and gender. Development assistance, by contrast, often addressed men in those societies. Feminist research has shed light on women's understanding of water resources (e.g., Feldhaus, 1995; O'Reilly et al., 2009), and gender was one of four top priorities identified by the UN Commission for Environment and Development in 1992 for improving water management. Movements have organized around environmental problems in aquatic and riparian habitats, including species extinction, wetlands preservation, groundwater contamination, and river restoration. During the 1990s, a large number of watershed movements arose in the US to address issues ranging from nonpoint source pollution to riparian habitat protection and landscape identity. Social scientists have sought to understand how these movements articulate environmental values (intrinsic, instrumental, and inherent) with political strategies, organizational dynamics, and environmental consequences.

A growing line of research focuses on political aspects of water management that behaviorist approaches failed to explain. These political issues include acute water problems faced by the poor, corruption and violence in water administration, inequitable access to water, vulnerability to flood hazards, and devolution of state authority to nongovernmental organizations (Mustafa, 2013). This work entails a shift from institutions to governance and politics (Baviskar, 2007; Mollinga et al., 2010). Brown and Ingram (1987) have sought to explain problems faced by low-income ethnic minorities by contrasting 'community' and 'commodity' values in water (Laurie, 2007). A broader, but fundamentally flawed, political framework was put forward by Wittfogel (1957).

Water and Power: Wittfogel's Theory of Hydraulic Civilizations

Wittfogel argued that irrigation agriculture had a formative role in the development of complex bureaucratic social organization, initially in the large arid floodplain environments of Asia which constituted a distinctively 'Oriental mode of production' that has, throughout history, threatened democratic societies. This contorted web of arguments was refuted soundly on empirical and theoretical grounds. Archaeological research on early irrigation systems showed that large-scale irrigation agriculture often followed complex state formation and had no consistent relationships with 'despotism' as Wittfogel defined it.

Notwithstanding these flaws, Wittfogel's work had three lasting implications for social research on water resources. First, it provoked three waves of research that included leading social scientists. The first wave included archaeologists and social historians who challenged the historical argument (e.g., Butzer, 1976). The next wave of students focused on structures of power in modern irrigation systems (cf. Maass and Anderson, 1978; Worster, 1985). A third generation of students became involved in the applied institutional experiments in irrigation management (Coward, 1980). The latter have shed light on the scales of state–society relations in water management, from community-based systems to state infrastructure and regulation (Zimmerer, 2011). The theoretical contributions of each group were sharpened by their response to, and continuation of, debates provoked by Wittfogel. This history of ideas has been accompanied by a rich body of historical research on water management including international rivers (Tvedt, 2010).

Wittfogel's second legacy was to draw together structural aspects of water management that were previously neglected or treated separately. His framework encompassed environmental conditions, technologies, economic patterns, property regimes, state organization, social class, and modes of social power. Discerning the relationships among these structures of water management remains a major challenge for water researchers. Current theorizations of power go beyond violent conflict to probing analyses of power relations and conflict resolution (Delli Priscoli and Wolf, 2009; Mustafa, 2013; Tal and Rabbo, 2010; Zeitoun, 2011). Research on water sharing and cooperation is limited but highly significant (Kreutzmann, 2000).

Toward Sustainable Water Management

Much if not most contemporary writing on water management concerns its unsustainability. Water policy has developed on a largely separate path from environmental management (Wescoat and White, 2003). Sector-based management of water for agriculture, cities, forests, and environmental quality has fragmented attempts at integrated management. A large body of work seeks to address these problems through a series of impact assessment methods, ranging from simple water stress and water poverty indexes (Falkenmark et al., 1989; Sullivan, 2003) to water footprint analysis of different economic activities (Hoekstra, 2013). At a broader conceptual level, the model of integrated water resources management (IWRM) has been put forward as a sustainable approach from the early 1990s onward by international organizations such as the Global Water Partnership. IWRM has sought to link water sector planning with environmental management and social equity in development and has gained acceptance over the course of a decade, only to facing increasing criticism for being unimplementable in scope and apolitical in substance (Mollinga et al., 2010). The field of sustainability science offers some hope for ways forward, but the evidence tends to rely upon locally sustainable precedents within a context that political ecology defines as inherently global as well as local (e.g., Crate, 2011; Gleick and Palaniappan, 2010). Research that links agro-ecological landscapes and irrigation systems helps bridge the longstanding gap between water and environmental management (Zimmerer, 2012). One of the interesting research challenges is how regions learn from successes in other places and earlier times (Kenney, 2005). While flows of knowledge, technology, and social relations are enormous, they have rarely been addressed with formal comparative methods (Mollinga and Gondhalekar, 2012; Wescoat, 2009).

Conclusion

Of the natural resources, water seems especially prone to social experimentation. Its fluid characteristics make it less subject to private control than land and thus more open to collective control. It is also more subject to social control than diffuse resources like the atmosphere, which has eluded most purposeful human management efforts. Water resources thus lie at a vital intersection between public and private control. The historical interactions between public and private water management and social research on them have yielded insights of broader significance for the social and behavioral sciences.

One important observation on the twentieth century's water research concerns the changing significance of social research in different parts of the world. In the late nineteenth century, US and Australian water specialists traveled around the world for models and lessons of water development in Asia, the Middle East, and Europe. The subsequent dominance of US and European researchers was based on advances in the theory and practice of integrated river basin development. But the most creative social research on water management in the late twentieth century occurred in developing areas that were open to institutional experiments in irrigation, domestic water supply, and sanitation (Lansing, 1991; Shivakoti, 2005; Uphoff, 1992). Transboundary water research has tended to focus on Asian and Middle Eastern water problems. US and European research remained innovative in the fields of floodplain management, urban water management, water quality, and water resources effects of global climate change. An emerging field of socio-hydrology strives to encompass these dimensions of the sustainability of water resource systems.

These observations point toward a number of opportunities for future inquiry, including: (1) collaborative research on transnational water problems; (2) research on social scales of water control from the local to the global; (3) critical assessment of trends from public water management toward private market-based approaches, and post-neoliberal water management; and (4) research on experiments in science-based policy, citizen-science, and adaptive management of complex water ecosystems.

Water Wars

Ashok Swain, Uppsala University, Uppsala, Sweden

© 2015 Elsevier Ltd. All rights reserved.

Abstract

It is often said that future wars will be fought over water. These water wars, defined as armed conflicts between two or more states over the scarce water resources, are predicted to take place over the sharing of international rivers. Sharing water is expected not only to increase competition and conflict, but also to contribute to build engagement and cooperation. In recent years, many water treaties have been negotiated and signed. However, these treaties face danger to their survival as allotted water in the existing sharing agreements in most of the cases is unable to meet the increasing demand. Possible impacts of global climate change have also brought further uncertainties to the peaceful sharing of scarce water resources.

Growing Water Scarcity

Water is critical for human survival, economic development, and the environment. Certainly, few other resources affect so many areas of the economy or human and environmental health. Seventy-five percent of the earth's surface is covered by water; however, most of it is saltwater, and much of the remaining quantity is stored in ice caps, glaciers, underground, within soil, in the atmosphere, and in living beings. Excluding lakes, only about 2000 cubic km of fresh water, found principally in rivers, is available for human consumption (Falkenmark, 1990).

More than 80% of this total global run-off is concentrated in the northern temperate zone, which hosts a small portion of the world's population (Postel, 2000). In the tropical and arid areas, where most of the population lives, the remaining water run-off resources are also distributed unevenly. Almost all of the developing countries are in the arid, semiarid, and tropical regions; many of them are facing severe water shortages. The world's population is now increasing by about 78 million people every year, and 95% of this growth is taking place in developing countries of Africa, Asia, and Latin America. This high population growth in the developing countries has multiplied pressure on fresh water resources (Swain, 2001). This problem is further exacerbated in these regions by their efforts toward rapid industrialization, massive urbanization, and agricultural intensification.

Developing countries are increasingly meeting growing water demand by building large dams for water storage, using a canal to divert water from one area to another or extracting ground water. The requirement for hydroenergy and commercial fishing has also contributed toward human intervention in water. Dam building, which has almost become obsolete in North America and Western Europe, is still considered the panacea for water shortage problems in many developing countries. However, dam projects submerge vast areas of land and forest and displace their inhabitants. There are millions of people who have lost their homes and livelihoods due to these large water projects (Swain, 2010).

The developing countries are primarily agricultural economies. To provide food to their growing population and also to achieve food security, these countries use proportionately more water on the agricultural sector than the industrial sector. Many developing countries already face serious problems in meeting rapidly increasing water demands of their population. In many developing countries, urban centers are rapidly increasing. Moreover, some developing countries are also industrializing faster. The expansion of urban areas and industrial sector has further added to the increasing water demand. With greater pressure being placed on the scarce water resources, overexploitation has resulted in acute shortages. Faced with such scarcity, water has increasingly become a source of social tension, bringing further competition and creating conflict within and between countries. However, these water conflicts not yet transformed to water wars, defined as armed conflicts between two or more states over the scarce water resources (Wolf, 1998). For a detailed analysis on conflict structure, please see the article Conflict: Organizational.

Water Scarcity and Conflict

The link between water resources and conflicts can be investigated in at least two different dimensions. First, in a conflict, the deliberate targeting of water storage facilities may be directly responsible for inducing water scarcity or reducing the water quality of the opponent. Thus, water scarcity becomes part of a military strategy and military behavior. Water supply is affected by conflicts, and fresh water resources also have the potential to cause or contribute to the emergence and/or escalation of conflicts among states or human groups.

Dispute over river water sharing usually comes up among the riparian states on three grounds: quantity, quality, and control. The incompatibilities of the last two issues (quality and control) are relatively easier to address with some financial and technical support (Swain, 2001). The quality issue, which had been the cause of disagreement among the riparian states in Europe's Rhine and Danube and North America's Colorado River in the past, has resulted in peaceful and cooperative arrangements. The disagreement over control of the Columbia River and Parana River in the relatively water abundant Americas has been settled for some time.

Water is not easily replaced; so, the problem of its reduced quantity is more difficult to address. The quantity factor in many cases threatens to destroy existing cooperative arrangements and forces the parties to take conflicting positions.

Global water consumption is rising steeply, and the lack of adequate supplies of water is a problem in many parts of the world. Water tables are falling increasingly in every continent. Several countries, most of them in the South, already face serious problems in meeting rapidly increasing water demand. Rivers are one of the most important sources of fresh water for human consumption. In scarcity situation, river water has increasingly become a source of tension as users are worried about the present or future availability of water supplies. Conflicts over water can be observed at different levels of society. Water issues can create new conflicting groups within a state, and in other cases, infuse incompatibility among the states. Even though water disputes are omnipresent they tend to become more complex and difficult when they concern international rivers.

Managing Shared Water Systems

According to the Trans-boundary Freshwater Dispute Database of Oregon State University, approximately half of the global fresh water is available through international basins in the world (UNEP, 2002). Overall, 145 countries have territories that include at least one shared river basin. Water has been frequently called the oil of the twenty-first century. Many believe that the dependence of these poor countries on an external water supply may force them to reorientate their national security concerns in order to protect or to preserve such availability. Such potential for conflict has brought global water issues into the arena of 'high politics.' United Nations (UN) officials and World Bank analysts regularly proclaim that "the previous war was about oil, the next war will be about water" (Morrissette and Borer, 2004).

Several countries are currently in dispute over the sharing of their common rivers. Some on-going international rivers inducing conflict are the Jordan, Nile, Euphrates–Tigris, Danube, Indus, and Ganges. With the exception of the Jordan basin (Cooley, 1984: 3–4), most international water conflicts have not led to physical violence, although the threat of the use of arms in these cases is not uncommon. As early as the mid-1980s, US intelligence services estimated there were at least 10 places in the world where war could break out over the shortage of fresh water supplies, with the majority located in the Middle East (Starr, 1991: 17).

Most developing countries require financial and technical aid and assistance to undertake large water projects. Very few countries can undertake expensive water projects on their own, coming at a heavy economic and political price (e.g., GAP project in Turkey, Three Gorges Project in China, and Narmada Project in India). In the post-Cold War period, it has become increasingly difficult to receive external support for a disputed project in an international basin. The end of the Cold War also stopped the alternative source of borrowing from the Eastern Bloc.

Water scarcity has caused a few minor skirmishes but no war has yet been fought between states. However, wars are very rarely fought over one issue. So, establishing water as the sole reason to cause violent armed conflict between two nation-states is not that easy. Water might have played a contributing role in a war through its contribution to food scarcity, population displacement, and ethnic alignment, which can lead to internal disturbances and political instability resulting in war. So, the real contribution of water scarcity to a war may not be properly examined through a conflict mapping data set, which only captures immediate causes. In-depth studies of individual wars might reveal the real contribution water scarcity has on instigating wars in different parts of the world.

Shared water is expected not only to increase competition and conflict, but also to contribute to building engagement and cooperation among riparian states. Due to mutual dependence, the withdrawal or pollution of river water of one riparian state can potentially not only lead to disputes, but also bring cooperation in the basin. Particularly in the last two decades, several competing riparian countries have moved toward establishing regimes and institutions for cooperation. Shira B. Yoffe and Aaron T. Wolf (1999) count the signing of 145 water-related treaties in the last century. There have been a number of very successful cases of cooperation among riparian countries that address pollution and management issues of their shared waters. The agreements among the riparian countries of the River Rhine, Colorado, and Parana are some of these examples.

Agreements on international rivers have not been limited to addressing water quality or management issues. In the last two decades, several international river basins have also witnessed a trend toward reaching agreements on quantity allocation as well. Competing riparian countries of the Mekong, Jordan, Ganges, Nile, and Zambezi Rivers have signed sharing arrangements in the 1990s. The signing of the agreements on these important rivers in conflict-prone regions has been regularly referred to downplay the possibilities of 'water war' scenarios.

River Water Sharing Agreements

An agreement can be more likely among the contending riparian states over the quantity allocation of a river resource, when there is enough unused water left in the river. Agreement on the Indus River system became a possibility in 1960 between two traditional rivals, India and Pakistan, because nearly 80% of the river water was running into the Arabian Sea, unused by both basin countries. One year before the Indus Agreement, another agreement on the sharing of the Nile River was reached between Egypt and Sudan. The 1959 Agreement become a possibility since a large amount of the run-off remained unallocated from the 1929 Agreement. However, with increasing water demand upstream and less availability of unused water, these rivers have already become a source of serious tension among the major riparian countries. The increasing riparian demand has also raised doubts about the continuation of the existing water sharing arrangements on the Euphrates–Tigris river system. The hope for further exploitation has not only enabled agreements for the Indus, Nile, or Euphrates–Tigris Rivers in the past but also facilitated agreements in recent years. Bangladesh signed the 1996 treaty with India with the hope to build a barrage on the Ganges at Pangsha, downstream of Farakka in Bangladesh. The 1995 Agreement signed among the lower Mekong basin countries became a possibility as the slow-flowing Mekong River

provides a lot of potential for further exploitation. The Zambezi river basin is another example of riparian cooperation based on the hope for the further exploitation.

Water-scarce riparian states have been able to find cooperative solutions in the last two decades rather than enter into violent conflict. Signing of agreements on water sharing may be easy, but the real problem is how to keep the agreement viable. The compliance part poses real challenges. The agreement needs to stand the test of time. Many agreements in recent years have been reached about how the water should be shared. In spite of reaching agreement, riparian discontent has not dissipated as many upstream countries believe they should have complete control over the flow of the rivers and withdraw water according to their demands. In some cases, where the downstream states are often more powerful in economic and military terms, they challenge upstream rights over the river flow, like Egypt, India, and Israel.

Global Climate Change and Uncertainties

Global climate change brings further uncertainties to the smooth functioning, even survival, of these recent international water agreements. With increasing temperatures and rapidly melting glaciers, lesser water supplies will be available to farms and cities during summer months when irrigation demand is high. Some parts of the globe may experience sizable reductions in precipitation, or significant changes in the timing of summer and rainy seasons. Climate change will increase supply side pressure for river water management, and global warming may also contribute to the demand side pressure due to increased demands in domestic, irrigation, industrial, and ecological use (Arnell, 1999).

As climate change can potentially affect water supply and demand patterns, sharing of scarce water resources in the arid and semiarid regions will become the most likely security challenges in the near future. Climate science has been able to provide a basic understanding of how the hydrological cycle will change at the global level, but the predictions of water demand and supplies at the regional and basin level is still far from reaching any consensus. The projected impacts of global climate change over fresh water may be huge and dramatic, but they will not take shape on the same scale in every geographical region. Even within an international river basin, the effects will vary depending on the location. This further enhances the uncertainties and anxieties over the water availability in the shared river systems. In this context, both domestic and international water laws and policies are not well equipped to meet the challenges posed by the global climate change (Eckstein, 2010).

Existing water sharing arrangements between the riparian countries of international rivers in most cases provide some mechanisms to adjust to the run-off variability while agreeing on allocation of fixed quota of water. Of 145 river agreements signed in the last century, approximately 37% dealt with quantity allocations (Wolf and Hamner, 2000). Variability of river water flows can very well reduce the longevity of these river agreements (Drieschova et al., 2009). Usually, the regular water sharing agreements tend to be based upon the assumption that any resulting shortages will be for a short duration only and that they can address the issue with temporary reallocation methods (Tarlock, 1999–2000). However, climate change can not only bring long-term increases or decreases to the average run-off of the river system, but also influence the variability of those flows that require flexibility to be the part of the water sharing framework to cope with emerging situation.

As global climate change brings long-term changes to the volume and pattern of run-off in shared river systems, it becomes crucial to examine the suitability of existing agreements to address this challenge. Climate-related changes might require comprehensive adjustments in the on-going water management structure of international rivers. This comprehensive effort might ask for the water sharing arrangements to be flexible and competent in allocating reduced and surplus water flow, maintaining certain water quality level, sustaining ecosystems, controlling flood, and protecting existing water development infrastructures. Thus, the river sharing arrangements need to have the provisions for information sharing, conflict management mechanisms, flexibility to adjust to the uncertainties, and endeavor for basin-based development strategy.

Basin countries must be under obligation to regularly exchange data and information among each other to monitor and manage changing conditions affecting shared water. In case of any dispute or disagreement over shared water management, there must be provisions available to basin countries to manage them as soon as possible. International river water management regimes and institutions require a flexible mandate to plan, operate, and implement, in order to cope with changing climatic conditions. The emerging unprecedented situation due to changes in climatic patterns requires basin countries to cooperate and act collectively (Swain, 2012).

There is no doubt that climate change poses extreme challenges to water resource management in international river basins in the South. Maarten De Wit and Jacek Stankiewicz (2006) demonstrate the dramatic potential effects of relatively small changes in rainfall due to climate change over the perennial drainage of the river. Moreover, climate change might cause extreme weather events, water shortages, changing sea levels, or melting glaciers that can generate serious threats to critical river water management infrastructure. While the importance of adjustment of flow variability in water sharing is crucial, many of the existing provisions within agreements are not adequate enough to meet the scenarios that global climate change models project. They lack enforcement and generally depend upon 'ideal' riparian behavior in case of eventuality. However, this approach may overcome run-off deficits in the short term, but climate change poses the risk of long-term flow reduction that would severely test existing provisions.

To reach an agreement that meets all competing and fluctuating demands for water in an international basin is in fact a very difficult task. Hydro diplomacy thus needs to adopt a total resource view where river water is seen as a key input for development and growth in the basin. The challenges are limited not only to technical and economic sectors, but also to crucial water sector reforms, which is political by nature. Moreover, the task of hydro diplomacy will no longer be limited to basin-based regimes and institutions; it must achieve effective water management in the face of climate change and must influence the supporting pathways from local, national,

and international policies and practices. In the past, river sharing matters could be effectively covered by a few negotiators trained specifically to deal with water issues. But today, hydro diplomacy needs not only to involve itself in an increasing range of fields (such as energy generation, food production, human rights, and health issues) but also to take into account the possible impacts of climate change (such as precipitation pattern, glacier melting, temperature increase, and rising sea water encroachment on fresh water systems).

Water Resource Governance and Managing Water Scarcity

There have been numerous endeavors to establish and strengthen international institutions and create an international legal framework for the management of international rivers. Global initiatives on the matter of fresh water have brought the international river sharing problem to the fore. International community is engaged in an on-going process toward establishing a common legal framework for the sharing of international watercourses at the global level.

In the first part of this century, the Territorial Sovereignty Doctrine (absolute sovereignty over waters flowing within a country) and the Natural Water Flow Approach (the river belongs to all the riparian states) came up in addressing the issues over the sharing of international rivers. Unfortunately, neither the territorial sovereignty nor the natural water flow approach provided a solution as they were based on an individualistic and anarchical conception of international law. The failure of these two legal approaches led some to think of sharing the rivers on an economic basis. According to this approach, the whole river basin is regarded as an economic unit irrespective of state boundaries and the waters are vested in the community of the users or divided among the co-riparian states. This joint approach includes joint planning, joint construction, joint management, and sharing of expenditure on construction and maintenance.

The idea of a single basin approach is attractive to economists and water engineers because it allows them to consider the international rivers as single hydrological units and plan accordingly. However, there are many difficulties involved in sorting out the externalities among the various riparian nations. The regulation and management of international river basins with so much concentration of power in the hands of nonpolitical commissions is an exception rather than the rule in the interstate practice. Owing to obvious limitations of states actually agreeing to joint development, not many examples are found employing this approach.

All these three above approaches were adopted and implemented in individual cases and due to their various limitations were not feasible for international practice. In the absence of any law to regulate international river systems, the International Law Commission after about 25 years of deliberations has submitted its draft in 1996 for the consideration of the UN General Assembly. Finally, the Convention on the Law of the Non-Navigational Uses of International Watercourses, adopted by the UN General Assembly on 21 May 1997, was submitted to the member states for their ratification. However, the process of ratification is moving along at a very slow pace.

By having both the principles of 'equitable utilization' and 'not to cause significant harm' in the text, the UN Convention was able to obtain a majority support in the UN General Assembly. Stephen McCaffrey describes the Convention as "a basket of Halloween candy: there is something in it for everyone" (McCaffrey, 1998). Even if this Convention is ratified by member states and becomes a legal framework, it will not be sufficient to address the problem of water sharing in different parts of the world. The sharing of international rivers among the riparian countries in different geographical regions is a problem of huge magnitude. Complex water disputes can only be solved by cooperation and compromise, not by a strict insistence on rules of law.

For successful and lasting cooperation on shared waters, there is need for a comprehensive approach to address the water scarcity issue. This comprehensive approach includes a number of measures to be taken at the basin level. The basin-focused measures include treating the river system as a single unit, involvement of both state and nonstate actors in water management, recognition of social and cultural contexts in water use, clear appropriation rules in water sharing, and an information sharing network among the riparian countries (Swain, 1999).

An international river, lake, or aquifer does not, by definition, respect national boundaries and as such, shared water systems should be treated as single units as regards the maximum utilization of their resources. The development of these shared water resources occurs most optimally at the basin-wide level and the whole basin should be regarded as one economic, ecological, and political unit irrespective of state boundaries. The regulation and management of basin organizations should be entrusted to an independent body, which is outside the political control of any single riparian state. Management of international freshwater systems should grow beyond the sphere of national sovereignty to achieve the best possible use of water, i.e., efficiency, equity, and environmental sustainability.

Not only states, but also nonstate water users must be eligible to participate as decision makers in the basin-based organizations. The sustainable use of fresh water requires user participation in all aspects of water policy and management in the basin. In order to construct sustainable basin-based water management institutions, contextual considerations are of the utmost importance. Existing traditions of rain water harvesting, water storing practices, and agricultural patterns are some of the issues to be taken into particular consideration while formulating basin management policy. It is necessary to have a set of clear rules and regulatory measures in the basin regarding water rights and environmental obligation. Basic needs for water must be identified and given priority. In several cases, riparian countries have unequal access to data and information due to differing data accessibility and asymmetric competence to process data. This asymmetric information can be scientific and/or strategic. For the smooth running of a river basin management regime, a functional information-sharing framework is required.

These basin-based initiatives need to be augmented and supported by various nation-state and international measures. Most of the developing countries are exposed to water stress or even water scarcity. The adoption of a supply management

strategy addressing only water shortage in the region is not nearly sufficient. To meet growing demands there is a need to minimize water use, particularly in the agricultural sector. Riparian states may opt for a planned allocation of agricultural activities to improve the productivity of water in their various regions in order to meet the future demand for food. There is a need to restrict and regularize the demand for the increasingly scarce water resources in the basin. The full-cost pricing of the water will create quantity restrictions for competing users. It will also force consumers to use water more efficiently than if there were no price tag on it or if it were available at a highly subsidized price. (For a detailed description of good water management, please see the article Water Resources and Sustainable Water Management).

External intervention and assistance can sometimes facilitate the negotiation of water resource sharing agreements. Riparian countries in the South are unable to establish institutional cooperative arrangements because of their concern regarding existing and future water rights. Mutual suspicion and uncertainties of reciprocal action obstruct constructive engagement. To overcome such obstacles, international actors can possibly provide credible and impartial international assistance to start the process of cooperation. Gradually, it could help to increase mutual trust and confidence among the basin riparian states in order to achieve collective action. Formation of river basin organizations encourages international collaboration and assistance for the river water development. As constraints on the resource grow, the opportunity cost for not cooperating is becoming clearer. The increasing scarcity of available fresh water per capita and lack of financial strength in the developing countries may gradually encourage the basin countries to cooperate in order to achieve an optimal benefit of the shared water. Basin-based development of irrigation, hydropower, water diversion, or flood control projects can provide riparian countries greater net benefits than what they could have achieved through purely state-centric development.

Conclusion

Water resource scarcity can be both the cause and the consequence of armed conflicts. In an armed conflict, as part of military strategy, the deliberate targeting of water projects may be directly responsible for inducing water scarcity or reducing the water quality of the opponent. Water supply is affected and polluted by conflicts, and fresh water resources also have the potential to cause or contribute to the creation of new conflicts. Nearly half of the global fresh water is to be found in more than 260 international basins. Many believe that the serious dependence of many countries on an external water supply may force them to reorientate their national security concerns in order to protect or to preserve such availability.

Shared water is expected not only to increase competition and conflict, but also to contribute to build engagement and cooperation among the riparian states (Wolf, 1998). The last 50 years have witnessed many water treaties being negotiated and signed. However, these water treaties face danger to their survival if they fail to receive support from effective institutional arrangement for proper water. Allotted water in the existing sharing agreements in most of the cases is unable to meet the increasing demand. The scope of further augmentation of river water in the arid and semiarid regions of the world is becoming limited due to possible impacts of global climate change. Global climate change has the potential to alter the water security landscape in a very significant manner in the near future.

Abstract

John B. Watson, the founder of the behaviorist movement in psychology, was born on January 8, 1878 in Travelers Rest, a poor village in South Carolina. He received his M.A. degree from Furman College, and his PhD from the University of Chicago in 1903. In 1908 he was appointed to chair a new sub department of psychology at Johns Hopkins University where he wrote most of his influential papers. Due to a love affair with Rosalie Rayner, a student at the university, he was compelled to leave academic life in 1920. He and Rosalie were married and Watson developed a very successful second career in advertising. In 1935, at the age of 37, Rosalie died of pneumonia. Watson was never to recover from that misfortune. He lived 25 more years, a sad, depressed man, and died on September 25, 1958. Watson believed psychology should become a science, and advocated behaviorism on the grounds that only behavior could be studied scientifically. He was a prolific researcher into a broad range of phenomena including homing patterns of birds, effects of alcohol on behavior, and acquisition of fear and conditioned reflexes in infants. His influence on contemporary psychology has been profound, although seldom acknowledged.

J. B. Watson the founder of the behaviorist school of psychology was born on January 9, 1878 in Travelers Rest, a poverty stricken village in South Carolina. His father deserted the family when he was 12. His mother, a deeply religious woman, sold what little they had and moved to Greenville, a larger town, in the hope of providing better education for the children. In 1894, through the help of their church, John was admitted to the Baptist Furman College, from which he graduated with an M.A. degree in 1900. He was then admitted to the University of Chicago where 3 years later he became the youngest person to receive a Chicago PhD He remained there until 1908 as Instructor and assistant to James Angell, the eminent philosopher. In 1904 he married Mary Ickes who was the youngest sister of Harold Ickes, the influential Secretary of the Interior in Roosevelt's 'new deal' cabinet. Harold disapproved of the marriage, and may have played a part in the problems Watson was to face later. In 1908 he moved to Johns Hopkins University as Assistant Professor and Chair of Psychology. Almost all of Watson's seminal work was produced in the relatively short span of the ensuing 12 years. In 1920 his academic career came to a premature end when he developed a love affair with a young student, Rosalie Rayner. Anticipating that the affair may lead to unwanted publicity for the university, Watson decided to inform the president of the university. At the interview the president demanded his immediate resignation which Watson instantly wrote. The anticipated scandal broke in newspapers some three months later, when his wife Mary filed for divorce. As soon as the divorce proceedings were complete, on December 31, 1920, Watson and Rosalie were married. Watson was penniless, having left everything he owned to Mary and Rosalie had been disowned by her parents, who disapproved of the marriage. For a time they stayed with friends in New York. Eventually, Watson was offered a position in the advertising agency, J. Walter Thompson Company. In accord with the company policy that all employees must have personal experience of selling, Watson was sent to New Orleans to sell fishermen's boots door-to-door. Upon returning to headquarters his ideas and proposals were so successful that within two years he had risen to the position of Vice President. Having reached the top of his profession, fallen, and risen to the top of another profession, Watson was to suffer yet another tragedy. In 1935 Rosalie died of pneumonia. She was 37. He was never to recover from this loss. He died a disappointed, depressed man on September 25, 1958 at, ironically, the Johns Hopkins Hospital in Baltimore.

In harmony with the spirit of his times Watson believed in the supremacy of science, and its power for resolving our social and personal problems. Psychology, he thought, must become a 'natural science.' His seminal paper, *Psychology as the behaviorist views it*, sometimes referred to as 'the behaviorist manifesto,' was published in 1913. Its essential arguments were that to be a natural science psychology must adhere to the principles that are basic to all sciences, including the principle that what is studied must be public, i.e. observable and replicable by more than one person. Therefore, the subject matter of psychology should be behavior and nothing else. These views came under severe attack from the psychological establishment for two main reasons: first, they implied that the work of the past several decades, based on the method of introspection, had to be discarded or at best, disregarded; and second, they conflicted with the established view that psychology studies the mind, the psyche, feelings, thinking, and the like. If psychology only studied behavior, what was to be made of such concepts? Watson's answer was that these concepts had no place in science. Thus, the controversy over behaviorism arose not as much from the proposal that the science of psychology should study behavior, as it did from Watson's insistence that it should study nothing else.

Watson wrote many scholarly articles, monographs, books, and popular articles developing his view of the behaviorist science of psychology. He believed the function of psychology is to 'predict and control' behavior which, when fully achieved, would result in the good society. He wrote 'behaviorism ought to be a science that prepares men and women for understanding the principles of their own behavior ... I wish I could picture for you what a rich and wonderful individual we

[†] Deceased.

should make of every healthy child if only we could let it shape itself properly and then provide for it a universe in which it could exercise that organization (1925). With reference to the intro-spectionists' efforts to obtain verbal reports of phenomena that occur 'inside' a person, he asserted that such events are no different from events outside the body and they are, just as behavior, fully amenable to objective, scientific investigation. Language is a form of behavior and, therefore, subject to behaviorist study. Personality is the result of 'what we start with and what we have lived through (1919). Since, as far as it was known at the time, what we start with could not be changed, personality could only be developed or changed by appropriately arranging the environment. Watson's statement 'Give me a dozen healthy infants, well-formed, and my own specified world to bring them up in and I'll guarantee to take any one at random and train him to become any type of specialist I might select—doctor, lawyer, artist, merchant-chief, and yes, even beggarman and thief, regardless of his penchants, tendencies, abilities, vocations, and race of his ancestors' is quoted in almost every textbook. However, the very next sentence is 'I know I am going beyond my facts and I admit it, but so have the advocates of the contrary and they have been doing it for many thousands of years (1925). The apparently deliberate omission of this sentence by his critics unfairly suggests an extreme claim that Watson did not make.

After his departure from academic life Watson continued to lecture, supervise research, and write on psychology. Between 1922 and the death of Rosalie he conducted a course on behaviorism at New School for Social Research, corresponded with Bertrand Russell, Yerkes, Titchener and others, many of whom contributed to his course as guest lecturers. His book *Behaviorism* (1925) was originally written as lectures for this course. His research with 'Little Albert' where he and Rosalie conditioned the fear response in the boy to furry objects is often cited, but his research with a large number of other infants is less known. In later studies he supervised the elimination of the fear response in doctoral research by Mary Cover Jones. His views on child rearing were extreme, arguing that the development of emotional ties with infants should be avoided and that parents should not hug and kiss their children. He advised parents to follow this, in a popular book written with Rosalie Watson (1928). Some years later he changed his position on this and expressed regret that he had advocated it.

The roots of behaviorism go back much earlier than Watson. Lloyd Morgan's book, *Introduction to Comparative Psychology* (1894) sets the beginning of 'animal psychology' which necessarily required research into behavior. The assumption that the principles discovered through research into animal behavior will also hold for humans began to gain strength. Further, Pavlov's discoveries of conditioning, Darwin's theory of evolution indicating a continuity across species, and Thorndike's theory of learning based on research into animal behavior contributed to a *Zeitgeist* for the emergence of behaviorism. Watson's doctoral research which was entitled *The psychic development of the white rat correlated with the growth of its nervous system* (published as *Animal Education*) emerged in this context. His major contributions were to articulate the prevailing ideas, explicitly to formulate behaviorism, and to elaborate the ideas and principles that follow from it.

Watson regarded himself primarily a researcher and often referred to himself as 'a laboratory man.' He was interested in broad range of phenomena and in finding new ways of investigating them. It is little known that he was a pioneer of what later came to be established as Ethology. Beginning in 1906 he spent two summers on the Dry Tortugas islands, off Florida Keys, studying the behavior and homing patterns of noddy and sooty terns. Between 1907 and 1915 he published eight papers on the homing behavior and spectral sensitivity of birds. He was also a pioneer of what is now known as behavioral pharmacology. In his last year at Johns Hopkins he had begun to investigate the behavioral effect of ingested alcohol, with the collaboration of Edward Thorndike at Columbia University. The project was abandoned when he resigned. In his second profession in advertising he continued to develop innovative ideas, and pioneered the technique of associating an attractive image with the product even if they are not related intrinsically. The first of these, showing pictures of attractive women in an advertisement for Pond's face creams was very successful, and the technique became established, lasting to the present.

In his relatively short span of years in academia Watson became one of the most influential individuals in psychology. He was president of the American Psychological Association in 1915, editor of *The Psychological Review*, *The Journal of Animal Behavior*, and *The Journal of Experimental Psychology* that he founded. His influence on psychology has been broadly profound and enduring, but seldom recognized. Throughout his career Watson maintained the practice of not replying to his critics. Nevertheless, the controversy over behaviorism continued unabated, and in time detracted from recognition of Watson's scientific researches. This, combined with his departure from academia in mid-career, produced the unfortunate result that all of his ideas about the science of psychology, personality, language, and his researches into conditioning were taken and developed by his contemporaries and by later psychologists, notably by B. F. Skinner, without due acknowledgment. Nevertheless, the signs of Watson's influence in the shaping of contemporary experimental psychology remain evident.

Wealth Distribution

Edward N Wolff, New York University, New York, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The principal assets in the USA in 2007 were homes (33% of total assets), business equity (20%), pension accounts (15%), and stocks and mutual funds (11%). The major sources of data on household wealth are estate tax data, household survey data, wealth tax data, and income capitalization techniques. Wealth inequality is typically measured by the share of total wealth controlled by the richest 1% of families. By this measure, there was a sharp increase in wealth inequality in the USA between 1983 and 1989, a decline from 1989 to 2001, and then a rise to 2010.

Wealth represents a stock of accumulated assets; income represents a flow of current output. Families not only receive income over the course of a year but also save part of their income in the form of housing, savings accounts, stocks, bonds, and the like. Such accumulated savings are referred to as wealth. The first part of this article explains why wealth, like income, has an important bearing on the well-being of families and individuals. The second part develops the concept of household wealth; the third discusses some of the problems inherent in its measurement; the fourth shows how the structure of household wealth has changed over time; and the fifth presents time trends in the inequality of wealth. Data drawn from the USA will be utilized to illustrate parts of the discussion in the text.

Wealth and Well-Being

Why are we interested in household wealth? Most studies use income as a measure of family well-being. Though certain forms of income are derived from wealth, such as interest from savings accounts and bonds, dividends from stock shares, and rent from real estate – income and wealth are by no means identical. Many kinds of income, such as wages and salaries and transfer payments, are not derived from household wealth; and many forms of wealth, such as owner-occupied housing, produce no corresponding income flow.

Moreover, family wealth by itself is also a source of well-being, independent of the direct financial income it provides. There are four reasons for this. First, some assets, particularly owner-occupied housing, provide services directly to their owner. This is also true for consumer durables, such as automobiles. Such assets can substitute for money income in satisfying economic needs. Families with the same money income but differing amounts of housing and consumer durables will have different levels of welfare.

Secondly, wealth is a source of consumption, independent of the direct money income it provides. With the possible exception of consumer durables, assets can be converted directly into cash and thus can provide for immediate consumption needs. This is also true for the equity in owner-occupied housing, because second mortgages and home equity loans are another source of credit.

Thirdly, the availability of financial assets can provide liquidity to a family in times of economic stress (such as occasioned by unemployment, sickness, or family breakup). In this sense, wealth is a source of economic security for the family over and above the income that it directly provides.

Fourthly, large fortunes can be a source of economic and social power that is not directly captured in annual income. Large accumulations of financial and business assets can confer special privileges to their holders. Such large fortunes are often transmitted to succeeding generations, thus creating family 'dynasties.' They can also enable individuals to influence the political process through large donations to candidates running for public office and to lobbyists pursuing the special interests of their clients. Thus, wealth holdings provide another dimension to household welfare over and above income flows.

What Is Household Wealth?

The conventional definition of household wealth includes assets and liabilities that have a current market value and that are directly or indirectly marketable. A typical list of assets includes owner-occupied housing and other real estate; cash, checking, and savings accounts; bonds and other financial instruments; corporate stock; equity in unincorporated businesses; and trust fund equity. This measure will be referred to as 'marketable household wealth' (or simply 'household wealth'), since it represents those assets over which the family or individual has control. This notion corresponds to wealth as a store of value and is used in conjunction with a standard national accounting framework.

Table 1 presents the balance sheet for the US household sector in 2007. The wealth accounts are first divided into two major categories: assets and liabilities. Assets consist of items owned by households which have a positive value to them, while liabilities are debts, which by definition have a negative value. The difference between total assets and total liabilities is called net worth or, simply, wealth. In 2007, total household assets amounted to US$73.5 trillion, total liabilities were US$ 11.3 trillion, and household net worth was US$62.2 trillion.

Assets are divided into three main groups. The first, tangible assets, include stocks of real goods that are both 'reproducible,' such as houses, and 'nonreproducible,' such as land. In 2007,

Table 1 Balance sheet of total household wealth in the USA, 2007 (billions of dollars)

Panel A: Marketable net worth	*Value of component*	*Percent of total assets*
1. Total assets	73 519	100
a. Tangible assets	32 384	44
– Owner-occupied housing	24 112	33
– Other real estate and undeveloped land	8272	11
b. Financial assets	14 807	20
– Liquid Assets: Checking accounts, cash, currency, time deposits, money market funds, CDs, and the cash surrender value of life insurance	4820	7
– Pension Accounts: IRAs, Keogh plans, and other retirement accounts	8918	12
– Bonds and financial securities	1069	1
c. Equities	25 115	34
– Stocks and mutual funds	8669	12
– Unincorporated business equity	14 772	20
– Trust equity	1673	2
d. Miscellaneous assets[a]	1214	2
2. Liabilities	11 271	15
a. Mortgage debt	8413	11
b. Other debt	2859	4
3. Net worth	62 248	85
Memo:		
a. Home equity[b]	15 699	21
b. Pension fund reserves	13 391	18
c. Consumer durables	4468	6

Panel B: Other concepts of household wealth	*Value of component*	*Ratio to net worth*
Marketable wealth	62 248	1.00
Marketable wealth plus consumer durables	66 716	1.07
Marketable wealth minus home equity	46 549	0.75
Augmented wealth	88 547	1.42
a. Pension wealth	7105	0.11
b. Social security wealth	19 195	0.31

[a]Gold and other precious metals, royalties, jewelry, antiques, furs, loans to friends and relatives, future contracts, and miscellaneous assets.
[b]Gross value of owner-occupied housing less outstanding mortgage debt.

The Transformation of the American Pension System: Was It Beneficial for Workers? W.E. Upjohn Institute for Employment Research, Kalamazoo, Michigan.

total tangible assets owned by households were worth US$ 32.4 trillion, which amounted to 44% of total household assets. The major tangible asset owned by households is owner-occupied housing (i.e., houses that are lived in by their owners). This accounted for 33% of total household assets. The second component consists of land, apartment buildings, other rental property, and other real estate held by households. This group made up 11% of all assets.

The second major group is referred to as financial assets. These are assets which function as money or are readily convertible to money. These are divided into three subcategories. The first of these are so-called 'liquid assets.' The most liquid of these are cash, demand deposits (checking accounts), and time and savings deposits, which function directly as means of exchange. Liquid assets also include money market funds, CDs, and the 'cash surrender value' of life insurance funds. Certain life insurance plans (called 'full life insurance') allow individuals to contribute to a savings fund, and the amount the individual can withdraw from this savings fund is referred to as its cash surrender value.

The second subcategory is pension accounts, such as IRAs, Keogh plans, 401(k) plans, and the like. These can be invested in a wide assortment of assets and are referred to as 'tax-deferred' because the accumulations in these accounts are not taxed until they are withdrawn. The third subcategory includes bonds, notes, and financial securities issued mainly by corporations and the government. Such securities are 'promissory notes,' by which the borrower agrees to pay back the lender a certain amount of money (the principal plus interest) at a certain date.

In 2007, financial assets constituted 20% of household assets. Liquid assets as a group amounted to only 7% of total assets, while pension accounts constituted 12%. Bonds and other securities amounted to a mere 1%.

The third major group consists of equities or ownership rights. A corporate stock certificate issued by a company represents ownership of a certain percentage of the company's assets. Unincorporated business equity refers to small businesses (such as a farm or a store) owned directly by individuals, in contrast to corporations which are owned through stock shares. A person's equity in an unincorporated business is the value of the business. The third item, trust fund equity, refers to bank deposits, securities, corporate stock, and other financial instruments, which are held in a special legal arrangement called a trust fund. In a typical trust, the actual assets are managed by a specially named administrator (often a bank), and the income earned from the assets in the trust is remitted to individual beneficiaries. Trust funds held for individuals are counted as part of household wealth.

As a group, equities comprised 34% of total household assets in 2007. Corporate stock shares and mutual funds made up 12% of total household assets, unincorporated business equity 20%, and trust fund equity only 2%.

On the liability side, the major form of household debt is home mortgages. A mortgage is a loan, issued normally by a bank and usually for a period from 15 to 30 years, that is used to finance the purchase of real estate property, particularly houses to live in. In 2007, mortgage debt comprised 75% of total household debt. The remaining 25% consisted of other household debt, including automobile and other consumer loans, credit card debt, and educational loans. Together, total household debt amounted to 15% of the value of total household assets.

Three other entries are shown in the bottom of **Table 1**. The first of these is home equity, defined as the gross value of owner-occupied housing less outstanding mortgage debt. This represents the amount of money a family could net from the sale of the house (after paying off its outstanding mortgage balance). Home mortgages amounted to 35% of the value of owner-occupied housing. As a result, home equity made up a smaller proportion of total assets than the gross value of owner-occupied housing – 21 versus 33%.

The second entry is the reserves (assets) of pension funds. These funds are accumulated mainly by corporations and

governments in order to pay pension benefits for their workers when they retire. In 2007, they amounted to 18% of total marketable household assets. Technically speaking, these reserves are not part of marketable household wealth, since households have no control over the assets in these funds and cannot directly draw on these funds. However, these reserves are held for the benefit of individuals and therefore have some of the characteristics of a trust fund. The third category, called consumer durables, includes automobiles, washing machines and other appliances, furniture, and other long-lasting household equipment. Cars are the major component of household durables, and altogether durables amounted to 6% of total marketable assets.

A theme that regularly emerges in the literature is that there is no one unique concept or definition of household wealth that is satisfactory for all purposes. One definition of household wealth is that it is the sum of marketable wealth and consumer durables. This concept is useful because although consumer durables provide consumption services directly to the household, they are not easily marketable and the resale value of these items is typically far lower than the value of their consumption services to the household. As shown in Panel B, the sum of marketable wealth and consumer durables amounted to US$66.7 trillion in 2007, which was 7% greater than marketable wealth.

A second concept of household wealth defines it as marketable net worth minus net equity in owner-occupied housing. This definition represents a more 'liquid' concept than marketable wealth, since one's home is difficult to convert into cash in the short term. It thus reflects the resources that may be directly available for consumption or various forms of investments in the short term. This concept totaled US$ 46.5 trillion in 2007 – 75% of marketable wealth.

One of the major developments since the end of World War II has been the enormous growth in both public and private pension systems. Even though such pension funds are not under the direct control of individuals, they are a source of future income to families and thus may be perceived as a form of family wealth. Moreover, as Martin Feldstein (1974) has argued, insofar as families accumulate 'traditional' wealth to provide for future consumption needs, the growth of such pension funds may offset private savings and hence traditional wealth accumulation.

A wider definition of household wealth will thus add some valuation of pension rights, from both public and private sources, to marketable wealth. Such a measure provides a better gauge of potential future consumption.

Augmented household wealth is defined as the sum of household marketable wealth, social security wealth, and pension wealth. Social Security wealth is defined as the present discounted value of the stream of future social security benefits, and pension wealth is defined as the present discounted value of future pension benefits (see Wolff, 1992, for a discussion of measurement issues). As is apparent from the definitions, these two forms of wealth are not fungible or marketable, since individuals cannot convert these assets into cash.

What is the rationale for including these two forms of wealth? The main motivation is that from the standpoint of an individual, a future guaranteed flow of income is in many ways like owning a financial asset. Indeed, there are marketable assets called 'annuities' which have precisely the characteristic of providing a steady stream of income after a certain time (or age) is reached. The anticipated social security (or pension) benefits that an individual will receive after retirement is comparable to such an annuity. From the individual's point of view, then, a guaranteed stream of future pension or social security benefits may be as much a form of wealth as money put into a savings account that will be drawn on after retirement.

According to my estimates, total pension wealth in 2007 was US$7.1 trillion and total social security wealth was US$19.2 trillion (see Panel B). Together, they amounted to 42% of marketable net worth. Social Security wealth by itself was thus larger than any other component of household wealth except owner-occupied housing.

Problems in Measuring Household Wealth

There have been four principal sources of data for developing household wealth estimates: (1) estate tax data; (2) household survey data; (3) wealth tax data; and (4) income capitalization techniques. Each has its characteristic advantages and disadvantages.

Estate Tax Data

Estate tax data was the first major source of data used for wealth analysis. When someone dies, that person's assets are said to comprise his or her estate; and estate tax records are actual tax returns filed for probate. Such data have a great degree of reliability since they are subject to scrutiny and audit by the State. Their main limitation in the USA, at least, is that the threshold for filing is relatively high, so that only a small proportion of estates (typically 1% or so) are required to file returns. In the UK the threshold is considerably lower, so that the majority of estates file tax returns. This is also true for some states in the USA, as well as Washington DC, which have their own estate tax requirements.

Another difficulty with this data source is that the sample consists of decedents. Since most researchers are interested in distribution of wealth among the living population, a technique based on 'mortality multipliers' is used to infer the distribution of wealth among the actual population. If mortality rates were the same for each group, then the wealth of decedents would constitute a representative sample of the living population and researchers could use the estate data directly. However, mortality rates are much greater for older people than younger people, so that different 'weights' must be given to the estates filed by decedents of different ages. Mortality rates are also higher for men than for women (i.e., women, on average, live longer than men), and also higher for black individuals than whites. As a result, estates are assigned a weight based on the inverse of the group's mortality rate and these are then used to generate the size distribution of wealth in the living population.

Estimates of wealth inequality based on this technique are, as might be expected, quite sensitive to the precision of the mortality multipliers. The estimates can have a very large standard error, particularly for the young, since there are very few of them in the sample. This means that the results are very

sensitive to to the profile of the deaths in a given year and may therefore not be very reliable for young adults.

There are two other problems associated with this technique. First, insofar as mortality rates are inversely correlated with wealth (i.e., the rich tend to live longer), the resulting multipliers can be biased (see Shorrocks, 1975). Most studies do try to correct for this problem by using mortality rates for the wealthy that are lower than for the population as a whole, due to the longer expected life span of the wealthy. Secondly, the distribution of wealth estimated by this technique is for individuals rather than for families. Changing ownership patterns within families (for example, joint ownership of the family's house) can affect estimated wealth concentration. For example, marital customs and relations have changed over the century. Married women now inherit more wealth and have higher wealth levels than they did in 1900 or 1930. This reduces *individual* concentration even if *household* wealth inequality does not change. For example, between 1929 and 1953, Robert Lampman (1962) reported that the percentage of married women among the top wealth-holders increased from 9 to 18%.

As a result, since most researchers are interested in the distribution of family wealth rather than individual wealth, additional imputations must be performed to infer family wealth from estimates of individual wealth holdings. These typically involve making assumptions about marriage patterns – in particular, the correlation between the wealth holdings of spouses (whether, for example, rich husbands tend to be married to rich wives or poor wives).

Another problem with this data source is underreporting and nonfiling for tax avoidance. Though the returns are subject to audit, the value of cash on hand, jewelry, houseware, and business assets are difficult to ascertain. Their value is typically understated in order to reduce the tax liability of the estate. Moreover, *inter-vivos* transfers (i.e., transfers of wealth between living individuals), particularly in anticipation of death, can bias estimates of household wealth among the living. If older people pass on wealth to their children just before they die, then their estates would tend to underrepresent the wealth of comparably aged individuals still living.

Estate tax data have been used by Atkinson and Harrison (1978) for the UK; and Lampman (1962), Smith (1984), Wolff (1996a), and Kopczuk and Saez (2004) for the USA. The long-term time series on wealth concentration for the UK and the USA are based on estate tax data.

Household Survey Data

Household surveys are questionnaires that are given to a sample of households in a population. Their primary advantage is to provide considerable discretion to the interviewer about the information requested of respondents. Their major drawbacks are that information provided by the respondent is often inaccurate (response error), and, in many cases, the information requested is not provided at all (nonresponse problems). Another problem is that because household wealth is extremely skewed, the very rich (the so-called 'upper tail' of the distribution) are often considerably underrepresented in random samples. An alternative is to use stratified samples, based typically on income tax returns, which oversample the rich. However, studies indicate that response error and nonresponse rates are considerably higher among the wealthy than among the middle class. Moreover, there are problems in 'weighting' the sample in order to reflect the actual population distribution. Household surveys have been used extensively in many countries (see Wolff, 1996b, for a survey).

Income Capitalization Techniques

The third source of wealth data is based on the 'income capitalization' technique, which is usually applied to a sample of income tax returns. The earliest use of this technique on US data was a 1939 study by Stewart. In this procedure, certain income flows, such as dividends, rents, and interest are converted into corresponding asset values based on the average asset yield. For example, dividends are capitalized into corporate stock holdings by dividing dividends reported in an income tax return by the average ratio of dividends to corporate stock in the economy as a whole. This technique when applied to a large sample of tax returns can provide an estimate of the size distribution of wealth.

This source also suffers from a number of problems. First, only assets with a corresponding income flow are covered in this procedure. Thus, owner-occupied housing, consumer durables, and idle land cannot be directly captured. Also, in the USA, state and local bonds cannot be estimated, because this source of interest income is exempt from federal income taxes. Secondly, the estimation procedure rests heavily on the assumption that asset yields are not correlated with asset levels (i.e., for example, that large stock holders will receive the same average return on their stock holdings as small stock holders). Any nonzero correlation between asset holdings and yields can produce biased estimates. Third, the observational unit is the tax return. Various assumptions must be made in order to construct family wealth estimates from tax unit wealth.

Wealth Tax Data

A fourth source is wealth tax return data, which are available in a number of European countries such as Germany, Sweden, and Switzerland. These countries assess taxes not only on current income but also on the stock of household wealth. Though there is typically a threshold for paying wealth taxes, population coverage can be considerably greater than that of estate tax returns. However, the measurement problems are similar to those of estate tax data. The filer has a great incentive to understate the value of his or her assets or even not to report them at all, for tax avoidance. Moreover, the assets subject to tax do not cover the full range of household assets (for example, consumer durables, pensions, and life insurance policies are often excluded). In addition, the observational unit is the tax return unit, which does not directly correspond to the family unit. Wealth tax data have been used extensively by Spånt (1987) for an analysis of wealth trends in Sweden.

Changes in the Composition of Household Wealth

There have been some significant changes in the composition of marketable wealth in the USA over the last three decades.

One of the most salient trends is the rising indebtedness of American families, with the debt–equity ratio leaping from 15.1 to 21.0% between 1983 and 2010 (see Table 2). The principal source of these increases is not rising consumer debt, like credit card balances. In fact, nonmortgage debt as a fraction of total assets fell from 6.8 to 4.5% over the period from 1983 to 2010.

Rather, the primary source is rising mortgage debt, including home equity loans and second mortgages, which climbed from 6 to 13% of total assets. Indeed, mortgage debt as a share of the value of homeowner's property increased from 21 to 41%. Whereas the total market value of homes remained almost constant as a share of total assets over this period, net home equity – the value of the house minus any outstanding mortgages – plummeted from 24 to 18% of total assets.

A second notable change is that pension accounts rose from 1.5 to 15% of total assets between 1983 and 2010. However, this increase almost exactly offsets the decline in liquid assets, from 17 to 6%. As a result, the explosion in the use of various pension type accounts, like IRAs, 401(k) plans, and other thrift plans, rather than increasing overall family savings, appears, instead, to have allowed households to substitute tax-deferred pension accounts for taxable savings deposits.

A third important change is the rise in the share of corporate equities and mutual funds in total assets, from 9 to 11%, despite the drastic drop in the stock market from 2007 to 2010. However, this result does not reflect the full extent of the growth in corporate stock holdings, because stocks are also indirectly held in mutual funds, pension accounts, and trust funds. If we include these, then corporate stocks, both directly and indirectly owned by households, rose from 11 to 18% of total assets.

Table 2 Composition of marketable household wealth in the USA, 1983 and 2010 (percent of gross assets)

	1983	*2010*
Principal residence (gross value)	30.1	31.3
Other real estate (gross value)	14.9	11.8
Business equity	18.8	18.0
Liquid assets[a]	17.4	6.2
Pension accounts[b]	1.5	15.3
Financial securities	4.2	1.8
Corporate stock and mutual funds	9.0	11.4
Net equity in personal trusts	2.6	2.4
Other assets[c]	1.3	1.7
Total	100.0	100.0
Debt on principal residence	6.3	12.9
All other debt[d]	6.8	4.5
Total debt	13.1	17.4
Memo		
Debt/equity ratio	15.1	21.0
Net home equity/total assets	23.8	18.4
Principal residence debt/house value	20.9	41.2
Stocks directly or indirectly owned/total assets[e]	11.3	17.8

[a]Checking accounts, savings accounts, time deposits, money market funds, certificates of deposits, and the cash surrender value of life insurance.
[b]IRAs, Keogh plans, 401(k) plans, the accumulated value of defined contribution pension plans, and other retirement accounts.
[c]Gold and other precious metals, royalties, jewelry, antiques, furs, loans to friends and relatives, future contracts, and miscellaneous assets.
[d]Mortgage debt on all real estate property except principal residence; and credit card, instalment, and other consumer debt.
[e]Includes direct ownership of stock shares and indirect ownership through mutual funds, trusts, and IRAs, Keogh plans, 401(k) plans, and other retirement accounts.

Recent Trends in Household Wealth Inequality

The final part of the analysis shows trends in wealth inequality in the USA since the early 1980s and illustrates the sensitivity of wealth inequality estimates to different definitions of household wealth.

The calculations shown in Table 3 indicate an extreme concentration of wealth in 2010. The top 1% of families (as ranked by marketable wealth) owned 35.4% of total household wealth. The figures also show that the wealth share of the top 1%, after rising steeply by 3.6 percentage points between 1983 and 1989, fell by 4.0 percentage points from 1989 to 2001, and then increased by 2.0 percentage points from 2001 to 2010.

The inclusion of automobiles in household wealth (the only consumer durable available in the wealth survey data) lessens the estimated share of the richest 1% by about 1 percentage point in each of the years. This reflects both the fact that automobiles are more widely distributed in the population than other assets and also that vehicles are very important in the portfolio of poorer and middle-income families. The data also show similar time trends – a sharp rise in wealth inequality between 1983 and 1989 followed by a decline from 1989 to 2001 and then a modest increase from 2001 to 2010.

Household wealth excluding home equity is even more concentrated than marketable wealth, with the richest 1% (as ranked by this concept of wealth) owning 42% of the total in 2010. The trend in inequality is similar, with the share of the top 1% gaining 4.0 percentage points between 1983 and 1989, losing 7.2 percentage points from 1989 to 2001, and then increasing by 2.4 percentage points in the ensuing 9 years.

Table 3 Wealth inequality trends in the United States, 1983–2010

Year	*Marketable net worth*	*Net worth plus autos*	*Net worth minus net home equity*	*Augmented wealth*
1. Percentage share of total household wealth owned by the richest 1% of households				
1983	33.8	32.6	42.9	NA
1989	37.4	36.1	46.9	20.3
2001	33.4	32.3	39.7	23.2
2007	34.6	33.6	42.7	25.1
2010	35.4	34.3	42.1	24.3
2. Gini index (Gini coefficient x 100)				
1983	79.9	77.9	89.3	NA
1989	83.2	80.7	92.6	66.3
2001	82.6	80.6	88.8	66.1
2007	83.4	81.6	90.8	68.4
2010	87.0	84.8	92.7	68.5

Note that automobiles are the only consumer durable included in the survey data.
Sources: 1983, 1989, 2001, 2007, and 2010 Survey of Consumer Finances, and Wolff, E.N., 2011. The Transformation of the American Pension System: Was It Beneficial for Workers? W.E. Upjohn Institute for Employment Research, Kalamazoo, Michigan.

Table 3 also shows the trend in the share of augmented household wealth owned by the top 1% of wealth holders as ranked by augmented wealth from 1989 to 2010 (figures on augmented wealth are not available for 1983). The addition of pension and social security wealth has had a significant effect on measured wealth inequality because pension and social security wealth, particularly the latter, have grown much faster over time than marketable wealth and because social security wealth is more evenly distributed in the population than marketable assets. The gap in the share of the top 1% between marketable wealth and augmented wealth was 17.1 percentage points in 1989 (37.4 vs 20.3%). Unlike marketable wealth, wealth concentration based on augmented wealth shows an increase between 1989 and 2007 and a slight decline from 2007 to 2010.

The Gini index, a broader measure of inequality, which reflects the full distribution of wealth and which ranges from one to one hundred, shows a similar rank order of inequality among the different wealth concepts. However, it also shows somewhat different time trends. According to the Gini coefficient, the inequality of marketable wealth rose sharply from 1983 to 1989, more or less stabilized until 2007, and then increased sharply in 2010. Similar differences are evident for other measures of wealth. These comparisons highlight the sensitivity of wealth trends to different measures of inequality.

Future research might most appropriately be focused on understanding the factors behind changing wealth inequality both in the USA and other advanced nations (household wealth data are not generally available for less developed countries, with the notable exception of China). How have relative wealth holdings changed among age groups, among income classes, across racial and ethnic lines within a country, between families with children and those without children, and across gender lines? How have wealth holdings changed among countries of the world? What are the respective roles of household savings and intergenerational wealth transfers in explaining wealth differences among individuals and between groups? What are the reasons for rising indebtedness among American families and how does this compare to other countries? These are some of the salient research issues that occupy current researchers in the field.

Abstract

Max Weber was one of the great figures in the history of social science, and is now recognized as a political philosopher. His most famous work, *The Protestant Ethic and the Spirit of Capitalism*, led to a larger life-long comparative project on the relation between capitalist development and religiously conditioned economic ethics. Weber also attempted to define the relations between social science and normative sciences in accordance with the fact value distinction, and to draw out the implications of the nonrationality of value choice for social science, which works with value-related descriptions, and for politics, which involves competing values.

Max Weber was born Karl Emil Maximilian Weber in Erfurt, Thuringia on April 21, 1864. His father, Max Weber (1836–97), was a lawyer from a family of wealthy industrialists and merchants with international connections whose core business was a linen factory in Oerlinghausen, in Westphalia. His uncle transformed this factory, which had been a traditional family concern, into a model modern business. *The Protestant Ethic and the Spirit of Capitalism* contains thinly concealed elements of this history. Weber's father was a younger son in this family. His father pursued a legal and political career, serving in the German Reichstag 1872–84. Politicians and intellectuals, particularly historians, frequented the Weber household in Berlin. His mother, Hélène (née Fallenstein) was highly educated, religious, and active in poor relief.

Weber entered the university in 1882, studying law, as well as economics, ancient history, philosophy, and theology, and entered into the student life of the time, joining a fraternity. He served the first year of officer training in the army at Strasbourg, where relatives of his mother's were prominent at the university. He returned to Berlin in 1884 and concentrated on law and legal history, simultaneously pursuing his legal education, taking exams, and completing military service. Levin Goldschmidt and August Meitzen instructed him in *Staatswissenschaft* and he became a doctoral student under Goldschmidt, also briefly clerking at the Royal District Court of Charlottenburg, and performing military service in Posen.

His dissertation, "Development of the principle of joint liability and the separate fund in the public trading company from the household and trade communities in the Italian cities" (1889), based on hundreds of Italian and Spanish sources, was well received. He joined the *Verein für Sozialpolitik* (Association for Social Policy) out of a concern with the 'Polonization' of the Eastern regions of Germany, and became involved politically in the *Evangelisch-sozialer Kongress*. He continued his academic work, receiving his Habilitation under Meitzen for 'Roman agrarian history and its importance for state and civil law' in 1891. During this period, the *Verein für Sozialpolitik* employed him for a study of "The conditions of the agricultural workers in East Elbian regions of Germany." The study, a huge empirical survey designed as the basis of policy recommendations, marked a new direction in his career. The recommendations were controversial, but made his reputation as an agricultural economist, and enabled him to secure a professorial appointment in *Nationalökonomie* at Freiburg in 1894. From there he was appointed to a similar position at Heidelberg.

A mental breakdown after the death of his father ultimately led him to relinquish his teaching duties, but eventually he returned to an active role as an editor and producing scholar. His major 'methodological' essays (posthumously published as his *Gesammelte Aufsätze zur Wissenschaftslehre* in 1922) included part one of *Roscher and Knies* published in 1903, 'Objectivity in Social Science and Social Policy' in 1904, part two of *Roscher and Knies* and 'Critical Studies in the Logic of the Cultural Sciences' in 1905 and 1906, and, in 1907, *Critique of Stammler*. With the 1904–05 publication of *The Protestant Ethic and the Spirit of Capitalism*, his work began to take several new directions. During this period Weber traveled to the United States, where he spent several months, appearing as an Agricultural Economist at the 1904 St. Louis World's Fair, and visiting American relatives. His experiences were the basis for some of his subsequent writings. He became fascinated by the revolution of 1905 in Russia, learning the language in 3 months in order to follow the unfolding events, and wrote extensively on them, from a point of view that emphasized matters of social structure. Over the next few years he completed his work on ancient agrarian economic life, and agreed to take over the editing of a work which evolved into the text now known as *Economy and Society*, which Weber was never to complete. He became engaged publically in questions of university policy, and also pursued inquiries into industrial psychology in the family textile works, an expression both of his interest in the rationalization of work and his recognition of the role of such psychophysical factors as fatigue in work processes.

Weber also played an active, though characteristically combative role, in two academic organizations, the Social Policy Association and the German Sociological Society. He was one of the founders of the German Sociological Society in 1909, but left soon after because of his views on the separation between scholarship and advocacy. These views, which later became famous, if not well understood, under the label 'value-free science,' were developed and elaborated in a complex and long-running dispute within the Social Policy Association. This dispute began largely as a political dispute over matters of policy but it escalated quickly and was

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61136-4

transformed by Weber and his brother Alfred into an accusation that their opponents in this dispute had confused considerations of value with objective policy considerations, a point that was particularly crucial for Weber, who rejected the bland statism of his monarchical socialist older colleagues. Weber articulated an elaborate rationale for his position that followed from his notion of the nonrationality of ultimate value choice. He also argued that maintaining this separation was part of the duty of university professors. This did not mean that Weber himself refrained from taking on a political role. He was an active participant in a number of political and diplomatic ventures and as a member of private groups attempting to influence policy.

Weber's role in what was to become *Economy and Society* expanded and he became author rather than editor, a task which together with the series of studies that comprised 'The economic ethics of the world religions,' occupied him until his death. Neither project achieved final form. During World War I Weber, a reserve officer, worked as a hospital administrator, until reorganization made his services unnecessary. When the outcome of the war became clear, he wrote a series of articles in the *Frankfurter Zeitung* on the future constitution. During this period he gave two speeches with parallel titles to the Munich Free Students Association, 'Science as a Vocation,' apparently in late 1917, and 'Politics as a Vocation' in early 1919, after which both were published. The speeches were an aggressive and telling challenge to the cultural and political optimism of the time, and in the Weimar era remained relevant, especially to the long-running discussion of the 'Crisis of the Sciences.' After the war Weber served as a member of a group invited to participate in *Reichsamt des Innern* (Office of the Interior) meetings which produced the general outlines of the constitution of what became the Weimar Republic (Mommsen, 1984), became a professor of economics at Vienna in 1918 and Munich in 1919, and unsuccessfully pursued a career in politics. His untimely death, 14 June 1920 in Munich, came when his influence among intellectuals was at its peak.

Weber's Early Work

Weber's habilitation dissertation, although he later dismissed it as a "one of the sins of his youth" (quoted in Tenbruck, 1987), together with an essay on 'The Social Basis of the Decline of Ancient Civilization' (1896) marked him out as an original scholar. The dissertation used his knowledge of medieval land tenure law to illuminate the Roman agrarian situation. It depended on the plausible but unprovable assumption that two of the different methods of mapping used by the Roman Colonial land surveyors corresponded to different types of land tenure: untaxed, roughly measured lease rights from public land, and precisely measured private taxed lots. He argued that the size of the private lots suggested that they were too small for subsistence, and that from the first the smallholders on this land had depended on access to public land to survive, but that the rich, who could pay for leases and work the land with slave labor, eventually cut off this access. He reasoned that the poor but free peasants were forced, by the inadequacy of their holdings, to assume labor obligations to landlords as rent, and later to be legally bound to the soil. When new slaves were no longer available, barracked slaves, who had enabled production for the market, had to be raised in status, freed sufficiently to encourage them to reproduce, making them essentially into serfs. Increasingly, money transactions were replaced by transactions in kind, the coastal commerce on which the slave produced surpluses depended vanished, and the cities diminished in power and in fiscal, and consequently political, importance for the state. The new rural economic order was manorialism *de facto*, so this was in effect an account of the origins of the medieval agrarian order.

The 1903–07 Methodological Essays

Contemporary disputes in ancient history, notably the 'Bücher–Meyer controversy' over a stage-theory of the development of the *oikos*, were formative for Weber. His most important methodological article, 'Objectivity in Social Science and Social Policy,' was published in 1904, on the occasion of the transfer of control of the *Archiv für Sozialwissenschaft und Sozialpolitik* to a team of editors of which he was the leading member. Weber argued that to construct an historical explanation, or even an object of explanation, requires conceptualization, which he examined in terms of the concept of ideal-types that he distinguished from mere classifications that simply sorted objects into categories. Ideal-types typically diverged from reality, or were applied to empirical cases from which they diverged, as in the case of ancient capitalism, but served the purposes of the historian by virtue of the fact that they allowed the historian to ask questions that are meaningful in the present. Thus, while ideal-types were indispensable to the historical disciplines, these disciplines were also prone to a particular kind of error. The mistake in each case is that something that is properly regarded as an idealization of a phenomenon is treated as a real force or a teleological process. In Weber's hands, this was a powerful means of methodological criticism. Not only did it serve to indicate how the developmental models of his near predecessors and contemporaries, including Marx, used the idealization to constitute the phenomenon it explained, it called into question the project of final conceptualizations of history or social life, as well as the cognitive status of such conceptual constructs as 'the state.'

The line between the parts of historical understanding that are relative and those that are nonrelative and factual is difficult to draw. In 'The Logic of the Cultural Sciences,' he spoke of the 'real causal processes' which our concepts give an intelligible form to. In 'Objectivity' he argued that 'genetic ideal-types' are themselves relative to a culture-bound historical interest: the calculation of probabilities is fully objective, but the selection and conceptualization of the conditions cannot be. These are inherent limitations of a social science that must operate with concepts which seek conceptual clarity but whose meaningfulness derives from and remains tied to sources outside the science itself: 'the language of life,' a language which is necessarily bound to a historical moment and its values (Weber, 2012).

This argument takes on a special significance in connection with his account of values themselves. Weber argued that scholarship could at best enable judgments about the adequacy

of means for ends, the consistency of ends, the separation between and the difference between factual and valuative considerations, but could not constitute the basis of either value judgments or the endorsements of policies, at least to the extent that the valuative purposes of the policy could not be given scholarly justification. Ultimate value choices, worldviews, religions, and national cultures were alike in that they were in the end matters of commitment, not reason, and consequently questions of 'superiority' were misplaced.

The Protestant Ethic Essay

These basic methodological ideas, and especially the idea of ideal-types, figure in Weber's 1904–05 essay, *The Protestant Ethic and the Spirit of Capitalism*. The core problem of the essay was to account for the disruption and replacement of traditional economic life, and, he argued, that it was in part the indirect effect of Protestantism. Reformation theology, and particularly Calvinism, altered the problem of salvation. The doctrine held that the Elect, those predestined for salvation, are called to worldly tasks and an ascetic lifestyle: worldly monasticism. But, Weber reasoned, the doctrine of predestination was psychologically intolerable, and produced deep anxiety, which had to be allayed by pastoral assurances that faithful work in a calling was a sign of election, creating a novel and powerful psychological sanction for conduct. The theological premise thus had the indirect effect of producing a personality that, in the appropriate setting, becomes the austere, the abstemious, and the rationalizing capitalist.

There are many controversial features of this account, some of which result from the fact that the doctrinal element of the ideal-type that Weber constructed only imperfectly corresponded to the theological doctrine of much of Protestantism in Europe. Nevertheless, the account is deeply compelling, in part because the depictions of the believer accord so well with a character type that unquestionably did leave a profound mark on Western culture. Weber closed the essay with some prophetic remarks about the course of Western culture, and an important analysis of the cultural situation created by the secularization of the 'ethic.' He observed that the rosy blush of its 'laughing heir,' the Enlightenment, has faded, and that the inexorable demands of the modern, rationally organized economy, enforce the organization of work into 'callings' but strip them of their religious meaning. He commented that even the accumulation of wealth takes on the character of sport, and the people in the machine of capitalism became divided beings, "specialists without spirit, sensualists without heart" (1958a).

In his late lectures on economic history, Weber restated the thesis with some different emphases, notably with respect to the rational organization of free labor, which Weber came to see as especially crucial, and indeed to be the distinguishing feature of modern capitalism in contrast to booty capitalism, trade, and political capitalism, all of which were found in the ancient world. The crucial moment was when "the production of goods was emancipated from all the bonds of inherited intelligence, and came under the dominance of freely roving intelligence" (1961), the moment in which the craftsman was replaced by the worker, and the owner of the firm supplied tools, exacted discipline, and assumed the risks. This change was, Weber thought, a precondition for the mechanization of work with the goal of saving labor costs, and in this sense rationalizing labor. Together with this was the rationalization of the use of capital generally, through rational accounting methods, rational price setting for the purpose of profit, and backed by calculable law. The worldwide expansion, and continued success, of these practices did not rest on the foundation of religious belief. Weber also provided an overview of other factors in the development of capitalism, such as calculable law, and other contingencies, like the availability of coal in Europe, without which, he argued, "the revolution in the means of work … might have stopped and modern capitalism in its characteristic form never would have appeared" (1961).

Economy and Society and the Economic Ethics of the World Religions

In the last decade of Weber's life he produced a major methodological text; 'The Categories of an Interpretative Sociology' (2012), a major systematic work, the incomplete work known as *Economy and Society*, and the bulk of his mature substantive work, 'Economic Ethics of the World Religions.' The essays that make up this work are overtly concerned with the question of why a rational capitalism based on calculability originated exclusively in the West. However, their larger theme is the general problem of the cultural specificity of the West, that is to say the peculiarity, in world terms, of Western political, economic, and legal institutions. But the uniqueness of the West requires an unusual explanation.

The general development of religious ideas corresponds to the development of particular social strata, with peasants having a strong affinity for magic and aristocratic classes for a kind of self-justifying, charismatic self-conception. These affinities tend to be relatively stable and do not work to transform the social structures in which they arise. The problem of explanation, consequently, is to identify the point of openness in which very specific kinds of innovations, namely those that have transformative effects on individuals or groups, might arise. The general promise of religion is health, wealth, and happiness. And the basic affinities to strata express these needs in forms specific to the strata.

The exceptional cases are the salvation religions, which offer rebirth or redemption, and more generally, religions that are doctrinally open to rationalization and that produce potentially transformative innovations through rationalization. Religious rationalization, however, while producing new coherence or consistency in religious doctrines, characteristically serves to produce discrepancies with other 'spheres' from which religious life is differentiating under the same pressure of circumstance. A general problem which all salvation religions must face up to is the problem of the relationship between destiny and merit, the problem of theodicy, which these religions develop in extraordinarily elaborate ways – ways which 'rationalize' the discrepancies by making the fact of evil or bad luck intelligibly consistent with the religious ideology, and also ways that are consequential for practice. The Chinese solution, for example, was to reconcile the two by recourse to popular magical practice, which in turn had

negative consequences: a "deep repugnance to undertaking any change in the established conduct of life because supernatural evils are feared" (1961). Ancient Judaism, in contrast, devised solutions that excluded and repudiated magic, and this carried over into Christianity and consequently into the Western worldview in a way that favored the eventual development of science and technology.

Weber pointed to many similar indirect effects of general institutional conditions, conditions that do not directly determine possibilities, but nevertheless greatly reduce the probability of developments in a particular direction. Rationalization, for example, means the attainment of greater consistency and completeness, but the two take various different forms for intellectuals and practical persons, such as merchants, and the direction that rationalization takes in a given situation or in the face of given problems is governed by many circumstantial contingencies. Weber saw the various forms and processes of rationalization as interacting with one another. Rationalization in one sphere, such as law, might create difficulties that require a response forcing greater rationalization in other spheres, such as the economic, which in turn present problems for the law which are resolved by further legal rationalization, thus producing a kind of dynamic ongoing process of mutually reinforcing rationalization. Occasionally Weber appears to slip into the error of regarding the rationalization process as itself a historical force, but these rare cases ordinarily can be interpreted in causal, and typically 'interest' terms, as when, for example, the rationalization of modern law on the continent is interpreted as driven by the status interests of law professors.

Economy and Society

Economy and Society consists of a typology of forms of social action, especially institutional action, together with extensive historical commentary on the types. Weber said that the claim to be made on behalf of the typology was its usefulness; and the elaboration of the typology is an extended demonstration of the uses to which the types could be put in analyzing actual historical forms, particularly of institutional structure, and characterizing their historical course of development as the product of the basic properties of the type, always with the caveat that these were idealizations rather than 'real' types with a teleological character.

The most famous of these typologies involves beliefs legitimating authority and the forms that were characteristically produced by these beliefs. The categories were charismatic, traditional, and rational–legal. These were ideal types, which almost never, if ever, appeared in reality in a pure form. Traditional authority is based on unwritten rules believed to have been handed down from time immemorial; rational legal authority rested on the belief in the validity of written rules produced according to written procedures, and charismatic authority is the authority of the extraordinary person. Weber had in mind of course such figures as Napoleon and Jesus Christ, but he found many more modest examples in Indian gurus and medieval battle leaders, and in each of these cases obedience rested not on either written or unwritten rules but on the direct influence of the exceptional individual himself. Weber was careful to point out such things as the attenuated charismatic element in the modern monarchy and the jury.

Charismatic authority, Weber observed, is inherently unstable, though its temporary effects, and thus historical consequences, may be great. Gradually the critical charismatic leader must support his followers materially and this marks the beginning of the transformation of charisma into the everyday. Charismatic regimes also face problems of succession, and the 'routinization' of charisma through ritual in order to pass on charisma to successors soon becomes transformed into something akin to traditional authority, or alternatively into a bureaucratic system.

The value of the ideal-type is not so much that it serves to predict as that it enables one to ask relevant questions or identify relevant causal processes. However, this process is itself governed by our cognitive purposes rather than something inherent in the historical world itself. Much of Weber's discussion of the historical case material is indeed about the logical unfolding of implications of basic ideas such as charisma or rational legal authority. However, there is no sense in which this unfolding is causally inevitable. It is rather that concepts like charisma are useful in making processes intelligible precisely because the elaboration of the idea corresponds to the kind of developments that historical agents, employing their own ideas, beliefs, and so forth, actually bring about in the course of their actions.

Weber as a Political Thinker

Weber was self-consciously part of the post-Bismarck generation, and an ardent nationalist who was deeply concerned about the problem of succession of leaders. Bismarck's career had shown how forceful and successful leadership produced popular acquiescence and even enthusiasm, but with the effect of making Parliament weak and irrelevant, and undermining party loyalty. Weber saw this form of popular leadership, exemplified for him by both the unelected Bismarck and the elected Gladstone, as a key to the nature of modern politics: modern regimes were mass democracies in fact, regardless of the forms of constitutions, because they required mass legitimacy and support to be effective. The selection of leaders, and beyond this the administrative machinery of parties, were constrained by the demands of effective electoral politics. He was concerned on the one hand that interest-faction parties, especially parties that inevitably were bureaucratically organized, would be effective electorally, but that this would assure the predominance of party hacks rather than figures who could act boldly as leaders. He responded by suggesting a presidential office in which the president required support in the form of a plebiscite rather than party support, and thus stood above and outside of party structures. Although this analysis supported a liberal and democratic republican form of government, Weber nowhere based his argument for this form of state on traditional liberal constitutional concerns, such as the preservation of rights or the expression of the will of the people, notions he regarded as mythological, but instead based it on the problems of selecting great leaders in the face of the modern need for popular support for the tasks of nation-building. Weber nevertheless had a strong interest in

democratization in the social and cultural sense, and a fascination with and respect for the kinds of popular institutions that he encountered in his American travels, particularly the sectarian congregations.

Many interpreters have noted that the Nietzschean language of greatness that Weber employed, as well as the specific concerns about freedom he expressed, are rooted in a morality of the value of 'personality' that is potentially in conflict with constitutional liberalism, and especially to its egalitarian elements. When he observed that in rational work organizations "each man becomes a little cog in the machine and, aware of this, his one preoccupation is whether he becomes a bigger one," and when he asked if "a portion of mankind (can be kept) free of this parceling out of the soul" (quoted in Mayer, 1956) his concern was with a form of freedom accessible only to the few. Yet Weber's argument proceeds on more than one level. On the one hand he presented the state as a tool whose distinctive and necessary means is violence, and traced the origins of the historical conditions that constrain the possible present forms of state. On the other hand he made the point that the state is a means not necessary merely to the achievement of his own values, but to the achievement of virtually all this-worldly values: only someone like a Tolstoyan Saint has no need of the state. For the rest, there are no alternatives.

Much of Weber's energy went into thinking about international politics. He was an advisor to one of the most persistent politicians of the *Kaiserreich*, Friedrich Naumann, whose book *Mitteleuropa* set out the German problem and its solution through the incorporation of Eastern Europe in a German dominated customs union with common institutions. Although Weber played no role in the writing of the book, it resonates with Weberian insights into the reasons for the superiority of North Germany in the sphere of production. Naumann's account of the dependence of Germany on the agricultural lands of eastern Europe and the implications of economic and export superiority on regional political relations anticipates not only Nazi *Grossraum* policy but the larger problem of creating European institutional forms that accord with German economic superiority. Weber, despite his concerns over Germany being drawn into the political problems of the Austro-Hungarian Empire, participated in 1916 in a working group created to support and inform German policy in the direction of a closer union. He took part in a semiofficial diplomatic initiative to Austria, and made recommendations about the future of 'Congress Poland' and was especially engaged in the Polish question, which he thought should be solved by an independent state dominated by Germany rather than an expansion of Austrian control, and reflected on Bismarck's policy toward the problem. These issues became irrelevant when the tide of war turned against Germany. When it was clear that the war was ending and the question of German guilt was going to play a role in the peace, he assembled a group of professors in Heidelberg to prepare a response, which led to his participation in the Versailles conference as part of the German delegation.

Although Weber's interests in international affairs led to a number of newspaper interventions, and was the basis for his reputation as a political 'Realist,' he never produced a major work in this area. Weber's ideas, however were absorbed by Hans J. Morgenthau, and played a foundational role in the 'Realism' Morgenthau articulated as an American Professor and founder of the modern field of international relations.

Weber's Reception

Weber was not employed as a professor during his most productive years, and exerted relatively little influence through the training of students. His primary personal influence was through a salon that he and his wife held in Heidelberg which attracted many of the best minds, and particularly the best young minds, of the university, across various disciplines. This group included Georg Lukács, Emil Lask, and Karl Jaspers. Jaspers portrayed him as an existentialist hero: "an idealized modern man who resolutely exposes himself to intellectual risks and lives through intellectual tensions passionately without accepting final resolutions."

The Nazi period cut off serious discussion of Weber, who was described in the intellectual circles that supported the regime with the derogatory term 'liberal,' a characterization that shaped the revival of interest in his work in the postwar period. Weber's 'liberal' admirers, such as Jaspers, promoted the idea that Germany would have been saved from Nazism had Weber been accepted as a political leader, and as a consequence, after the Second World War, Weber was reinterpreted as a precursor of the new federal republic and its form of liberal democracy. Mommsen attacked this interpretation in his 1959 dissertation, later revised (1984), which noted Weber's attitude toward the normative premises of conventional liberal constitutionalism and suggested that his devotion to the idea of great leadership placed his thoughts uncomfortably close to the fascist *Führerprinzip*. Mommsen's work produced a controversy that broke out in a visible way in the 1964 commemoration of the centennial of his birth, when the thesis was radicalized by Marcuse and Habermas. Mommsen later stressed that he did not believe that Weber's own intentions had been antidemocratic in the Nazi manner, but that nevertheless "it crossed the boundaries of the traditional understanding of democracy and was amenable to reinterpretation in an anti-democratic sense" (1984).

Weber's thought appears early in the United States, but not as a founding figure of sociology, because he had no 'system' of the sort that other German and American thinkers had, and was only intermittently identified as a sociologist. Economists first translated his work: Frank Knight his *General Economic History*, based on student lecture notes and some added material from earlier work, Talcott Parsons his *Protestant Ethic*, the argument of which was popularized in Britain by R.H. Tawney. After the Second World War, the American social sciences, and especially sociology, were exported, in part as an alternative to Marxism, and Weber's ideas, understood primarily in American terms, became influential in the UK and in Germany itself. The characteristic emphasis was on value-free science and the rejection of ideological thinking, and on specific sociological concepts, such as charisma and bureaucratization, and on Weber's rejection of the Marxist claim of primacy of material over spiritual or institutional explanation. Weberian approaches typically were seen as emphasizing the practical demands of bureaucracy, or the autonomous role of interests other than

economic interests, such as ideal interests. The notion of the Protestant ethic fit with analysis of modernization and development of the sort that were part of the American response to third world and anticolonial movements, and were generalized and applied to such countries as Japan.

Weber came to be regarded as a distinguished forebear of antipositivist sociology by virtue of his use of the terms 'meaning' and 'understanding' to differentiate his own approach to sociology. The refinement and appropriation of Weber's idea of an interpretative sociology by phenomenologists such as Alfred Schütz became one source of a phenomenological approach to sociology. Weberian ideas were also conveyed through the writings of such figures as Karl Mannheim and Norbert Elias, but in forms increasingly distant from Weber's own thought. This set the stage for a series of rediscoveries within sociology of 'the original' Weber so that the 1980s and 1990s saw within sociology, and especially in the work of such writers as Wolfgang Schluchter, and more generally in connection with the *Max Weber Gesamtausgabe* project, a much more disciplined return to Weber's original concerns, and a vindication of the importance to Weber of such basic problems as the problem of Western uniqueness.

Although in his final post and through much of his teaching career Weber was an economist and economic historian, and the early reception of Weber in the United States was facilitated by the major Chicago economist Frank Knight, and by Talcott Parsons, then a junior faculty member in economics at Harvard, Weber's influence on economics and economic history has been limited. But within political science and sociology, by the end of the twentieth century, a great many of the fragments of Weber's thought had become part of the standard conceptual tool kit. It is doubtless a result of Weber's gift as a clarifier of concepts that these tools have shown such an astonishing staying power. In many cases, such as the concepts of charisma and Protestant ethic and the term 'conviction politician' derived from Weber's *Gesinnungsethiker*, the concepts have passed into common usage.

'Weberian' as a description of present scholarship means somewhat different things in different disciplines. In sociology, it means a focus on institutions and institutional forms and an avoidance of abstract assertions about 'society' not grounded in particular specifiable institutions, such as citizenship. In political theory, it means a rejection of value theories that employ Kantian notions of duty and the rational justification of authority or Rawlsian notions of justice in favor of a recognition of the persistence of rationally irreducible conflicts about ultimate ends. In international relations, it means Realism and the recognition that national interests, modified by variant conceptions of national interest and world images, remain the fundamental driving factors in international politics.

Abstract

Weberian modes of thinking emerged gradually in the twentieth century. Max Weber did not found a school of thought. The posthumous collection of his main work provided a starting point for renewed interest in his ideas. Beginning in the 1920s American scholars discovered Weber's work for reasons of their own, supplemented later by a generation of German-speaking émigrés. The institutionalization of Weberian analysis was a postwar phenomenon, encouraged by professional needs and controversies in the sciences. Today a Weberian paradigm has emerged as one of the principal ways of thinking about society and human affairs.

The formation of the kind of social thought known today as 'Weberian' has an unusual history. The main characteristics of a Weberian approach, perspective, or theory are closely associated obviously with the work of Max Weber (1864–1920), and yet Weber himself never promoted a distinctive school of thought or encouraged a like-minded attachment to any of his leading ideas. Contestation seemed to be his middle name. Weber was not a normal scholar in the ranks of the professoriate. He was academically active for barely 7 years at five different universities at the beginning and end of his adult life, published no books after his dissertation and habilitation, and invested his energies in editorships, scientific essays, handbook articles, newspaper commentaries, encyclopedia entries, polemical tracts, and occasional political writings and speeches. His intended audiences – professional and public, scientific and political – were quite varied. To an outsider his interests could appear unfinished and lacking in focus: an array of topics from the ancient to the modern world, approached from the contrasting perspectives of history, philosophy, law, political economy, economic history, political science, and the new science of sociology. Indeed, Weber's actual published work remained a mere torso of what might have been achieved. In view of his life accomplishments and habits of thought, it seems extraordinary that today we can speak confidently of a distinctive Weberian mode of analysis.

How and why did this development come about? What conditions had to be present for the emergence of a kind of thinking inspired by Weber and his intellectual example? What were the steps taken during the twentieth century that led select groups of scholars to promote Weber's work, to borrow his concepts and ideas, and to extend his questions in new directions? Sometimes it was a matter of direct appropriation, on other occasions the identification of a common problematic traceable to Weber's thinking. Weber liked to speak of a singular concatenation of circumstances in history leading to a particular outcome, and so it was also with Weberian social thought itself: an unusual configuration coalesced to yield what has been called by some today the 'Weberian paradigm.'

Consolidation of the Work

No body of thought can gain paradigmatic status without a textual basis that contains a set of puzzles to be solved and model problems inviting further investigation. When Weber died unexpectedly in 1920 his work was left unfinished and disorganized, the manuscript of *Economy and Society* consisting in large part of notes and scribbled analyses left on his desk. As scholars have long recognized, it is thanks primarily to Marianne Weber (1870–1954), whose biographical comment 'Max Weber's desk is now my altar' (Hanke, 2009), identified in striking prose the commitment to rescue and immortalize her late husband's reputation. Assisted by some of his last students, such as Melchoir Palyi (1892–1970) and Siegmund Hellmann (1872–1942), she compiled and conceptualized the foundation of what came to be understood as the Weberian legacy.

In Marianne's rendition the work consisted primarily of seven edited texts and collected essays and papers. Max Weber himself assisted with the publication only of the first volume of the *Collected Essays in the Sociology of Religion*. Virtually everything else was a product of Marianne's selections and choices as an editor:

- *Collected Essays in the Sociology of Religion*, 3 vols., 1920/1
- *Economy and Society*, 2 vols., 1921/1922; 2nd enl. ed. 1925
- *Collected Political Writings*, 1921
- *Collected Essays on the Theory of Science (Wissen-schaftslehre)*, 1922
- *Collected Essays on Social and Economic History*, 1924
- *Collected Essays on Sociology and Social Policy*, 1924

The sole exception to Marianne's editorial largesse was the Munich lectures on economic history compiled from student notes by Hellmann and Palyi:

- *General Economic History*, 1923

This specification of Weber's interests and topics – religion, economy, law, politics, science, sociology, social relations, and policy – and the ordering of his writings remained the standard until the revisions introduced by the comprehensive critical–historical collected works, the *Max Weber Gesamtausgabe*, that

began publication in 1984 and is only now close to completion. The new collected works promised to establish an authoritative basis for Weber's contributions and to open new avenues for interpretation. But until this century the meaning of the appellation 'Weberian' depended largely on the work Marianne placed in the public domain, supported by the interpretation provided by her own comprehensive biography of her husband's life and work (1926/1988).

The availability of original sources made possible the early reception and translation in the 1920s of Weber's work primarily in two locations: Japan and the United States. In Japan a questioning of capitalist modernity and the role of religion produced an early and independent intellectual perspective, with Weber's *General Economic History* translated in 1927, the same year as the first English translation, and Kajiyama Tsutomu's translation of *The Protestant Ethic and the Spirit of Capitalism* following in 1938. However, for a variety of reasons, including the postwar internationalization of science, the emerging prestige of American universities, and the hegemony of the English language, the appropriation of Weber's work in the United States was especially crucial.

The structural and organizational conditions for the success were set in motion by three sequential developments: first, starting in the 1920s the translations, analyses, and promotional activities of American scholars such as Frank Knight, Talcott Parsons, Edward Shils, and C. Wright Mills; second, the teachings, writings, and translations of the large number of Weimar era émigrés, such as Hans Gerth and Albert Salomon, who fled Nazi Germany in the 1930s and joined universities in the United States; third, the rapid postwar extension of interest in Weber in new directions, expressed in an outpouring of English translations and the institutionalization of his thought in American university curricula and the empirical and theoretical canon of the social science disciplines. These developments in turn provided the basis for the fourth phase: the return of Weberian thought to Germany, and its simultaneous renewal, growth, and extension worldwide.

American Appropriations

The earliest English translation of Weber's work, the student lecture notes compiled as *General Economic History* (1927), was produced by Frank Knight, the founder of the first Chicago school of economics. Knight may seem an unlikely candidate for this honor. But his lifelong interest in Weber grew out of a fascination with the historical origins of modern capitalism and the possible role played by cultural factors and religious beliefs. The Munich lectures seemed to Knight to represent Weber's most mature reflection on these topics. Pursuing similar interests, the young Talcott Parsons was introduced to Weber's work as a graduate student in Heidelberg in 1925. He first read the preface and the essays on *The Protestant Ethic and the Spirit of Capitalism* in the first volume of Weber's *Sociology of Religion*, finding the narrative so compelling that he became immersed in the text 'as if it were a detective story' (Parsons, 1980: p. 39). Studying with Alfred Weber (Max's younger brother), Karl Jaspers, and Karl Mannheim (who was teaching a seminar on Weber), Parsons was soon inspired to write a D.Phil. dissertation topic on capitalism in recent German scholarship. At the same time a proposal arrived to translate a major part of Weber's sociology of religion. With Marianne Weber's support the result after overcoming many obstacles was the book published as *The Protestant Ethic and the Spirit of Capitalism* (1930), in many ways the sacred founding text of Weberian analysis.

The two translations by Knight and Parsons survived for nearly 20 years as the main public sources of knowledge about Weber in English. The textbook quality of the translated Munich lectures, a collection of notes that Weber never saw or corrected, which in any case omitted the conceptual introduction, rendered the book a poor candidate for setting a research agenda. *The Protestant Ethic*, on the other hand, was provocative and controversial from the start. Weber's intellectual daring inaugurated discussion of an alleged 'Weber thesis,' which held in brief that the ascetic Protestant ethic or ethos, oriented toward worldly action and mastery of the world, was one of the important historical factors in promoting the emergence of a 'capitalist spirit.' Weber found this spirit exemplified in the homilies of Benjamin Franklin praising the virtues of personal accomplishment and work in a vocation. He argued further that the social carrier of the ethos was not the compulsory association of a 'church,' but rather the voluntaristic 'sect' in which moral testing of the individual was a condition for membership.

In this early intellectual context, then, to follow a Weberian line of thinking meant essentially (1) to accept as an instructive research hypothesis the proposition that certain kinds of cultural factors can have a profound effect on material economic relationships; (2) to work in the sociology of religion with a basic conceptual distinction between church and sect; and (3) to acknowledge as a methodological principle the use in social analysis of ideal or pure types, such as the construction 'Protestant ethic' or 'capitalist spirit,' as important heuristic devices.

Of course Weber's work encompassed much more than the ideas contained in Knight's and Parsons' translations. Among small circles of scholars efforts were also underway to recover other aspects of Weber's work. In this respect, the most significant fugitive publications emerged at the University of Chicago, where in the 1930s Edward Shils had begun translating numerous Weber texts. His passion for translating Weber focused on selections from the philosophy or theory of science essays collected by Marianne Weber, which included 'Science as a Vocation.' He also attempted the challenging first chapter of *Economy and Society* and 'Politics as a Vocation.' Like Parsons, Shils engaged with Weber's thought for personal edification and out of a sense of intellectual adventure, remarking in retrospect that "reading Max Weber was literally breathtaking. Sometimes, in the midst of reading him, I had to stand up and walk around for a minute or two until my exhilaration died down" (Shils, 1981: p. 184).

Encouraged by Knight, his teacher, Shils began circulating his work to students and faculty in mimeograph format. The texts became important in the effort to define, reform, and integrate the University of Chicago's social science curriculum. Coming to fruition late in the 1930s and supported by the University's President, Robert Hutchins, these pedagogical innovations were the first important institutionalization of a selection of Weber's texts and ideas,

such as the distinction between class and status, the conception of social action, the typology of authority or 'legitimate domination' (*Herrschaft*), and the concept of charismatic leadership.

The introduction of translated Weber texts in the classroom occurred not merely because of professorial interests, but for practical pedagogical reasons in an era when the social sciences were being defined and disciplinary boundaries drawn. In the United States, the debates were intense at Chicago and Harvard, and at public institutions like the University of Wisconsin. Faculty were concerned not only about disciplinary distinctions, but also about countering parochial tendencies in scholarship and integrating knowledge across the social sciences. From this point of view Weber's work offered breadth of coverage, conceptual richness, methodological acumen, and empirical and historical grounding – in a word, a vision of the sociohistorical world and the sciences investigating human affairs. The work's world–historical sweep offered a route to professionalization that could attract enthusiastic support, and it carried the promise of having unquestioned intellectual authority in the battles playing out in the sciences. In the classroom the innovation even took a specific form: armed with Shils's translations, instructors at Chicago addressed the pedagogical questions in the social sciences by placing major portions of Weber's dense prose in the hands even of the uninitiated undergraduates.

This was the kind of educational laboratory in which Weber's ideas began to grow and take root. A more complex and differentiated view of Weber began to emerge: not only the author of the Weber thesis, but also the theorist of bureaucracy and the state, the analyst of legitimacy and authority, the inventor of a new concept of charismatic authority, the defender of an ideal of scientific inquiry free from partisanship, the advocate of a political ethic of responsibility, the theorist of rationality and rationalization processes. Weberian thought started to come of age: it had become more timely, interesting, and challenging.

The early translation of Weber's work into English marked a breakthrough to a new phase in the reception of his ideas. But there is always a politics and sociology of translation. The early work of Parsons and Shils introduced a certain kind of conceptual terminology that assumed a life of its own, often based on the translators' outlook or on the current state of scientific discourse. The act of translation is always an act of interpretation, or more strongly, *mis*interpretation – a sometimes subtle distortion of the original, exaggerating some connotations and deeper intuitions while diminishing others. Citing one famous example, should *Herrschaft* translate as 'authority,' 'domination,' or 'imperative coordination'? The language favored by Parsons and Shils that gained ascendancy in coming decades tended to emphasize the behavioral and causal side of Weber's conceptual syntax, downplaying or avoiding the complexities in concepts like *Entzauberung* (disenchantment) or *Lebensführung* (life-conduct, the way one leads one's life). Subsequently, numerous debates were triggered by such choices and their intellectual consequences: distinguishing the author's actual views from those imposed by the translator, rediscovering an essential but forgotten concept, or reconstructing the theory on an alternative textual basis.

Émigré Perspectives

The second major source of knowledge and interpretation came from those scholars and intellectuals who emigrated from Germany in the 1930s, and who began to contribute to American intellectual life and to staff university social science departments. Some had known Weber personally or experienced him as a teacher and lecturer. They had an effect on the recognition of Weber's work and the growth of interest in some of his key concepts, such as charisma, power, and bureaucracy. In addition to Chicago, in this respect in the 1930s three other universities with prestigious graduate programs became crucial: Harvard, Columbia, and Wisconsin. To this group one should add the New School for Social Research in New York, a university in exile and home to numerous transplanted German-speaking scholars having a deep appreciation for Weber's writings.

Some of the émigrés were especially important for the interpretation, extension, and application of Weber's ideas. Alexander von Schelting is one example. Having met Parsons in Heidelberg, von Schelting later traveled to the United States on a fellowship and renewed their exchange of views. Associated at first with Howard Becker at Wisconsin, he then found a position at Columbia, where he taught a joint Weber seminar with Shils. Von Schelting served importantly as a bridging figure from the Weimar era methodological focus on Weber's work to the reinterpretation of Weber's conception of social action. It was the social action 'frame of reference' that began to preoccupy Talcott Parsons, and for that purpose von Schelting became Parsons's leading authority: the chapters on Weber in *The Structure of Social Action* (1937) bore the imprint of his guidance.

Hans Gerth was another émigré scholar who contributed significantly to the transmission and dissemination of Weber's work. In some ways his role was unique. Associated in Germany with Mannheim, Gerth ended up in 1937 exiled with Mannheim in London in precarious circumstances. Encouraged by Parsons and Shils, in 1940 he was able to find employment in Becker's sociology department in Wisconsin. It was a propitious relocation, for one consequence was Gerth's encounter with two ambitious graduate students: C. Wright Mills and Don Martindale. The Gerth and Mills and Gerth and Martindale partnerships produced some of the most important postwar Weber texts.

At the New School for Social Research many of the émigrés were thoroughly familiar with Weber's work and promoted a broader and more eclectic view of the subject than that espoused by Parsons. In this setting, for example, Albert Salomon's interests took a systematic turn, and in the first issues of Social Research (1934/35) he presented one of the earliest précis of Weberian thought, a survey of the methodology, politics, and sociology for a general audience. His view of the work heralded the emergence of a Weber at variance with the professional sociologist and specialized historical economist put forward previously by American scholars.

Generally speaking, the turn to Weber among the émigrés had to do with several fundamental issues. There was a sense that if one wanted to engage in social research, then one had to come to terms with the figure of Max Weber, widely credited as the most important thinker of their times. As a self-described

outsider, Weber also took on the function of providing orientation to the experience of displacement and homelessness. The rationale for such an appropriation was to be found in the work itself, since Weber could be read to have confronted the specter of capitalist modernity, writ large in America, with an acceptable cosmopolitan and critical sensibility familiar to a European. The result of this émigré perspective was then a different kind of Weber, more attuned to the critical problematics of modern life, the power of the modern bureaucratic state, and the demands placed on the scholar and teacher confronting a world in turmoil. As Franz Neumann formulated the change, previously Weber's work had been reduced to its least inspiring dimensions, but now in America under new conditions it took on a life of its own and broke free of superimposed schemes that tamed its real potential. At Chicago in international relations Hans Morgenthau seemed to prove the point by adapting Weber's political realism to an entire field of inquiry.

In the Columbia University setting émigré scholars like Neumann and Theodore Abel joined others in the kinds of discussions emanating from the New School in Lower Manhattan. Neumann thought Weber's appeal for historically and theoretically grounded inquiry, combined with intellectual sobriety, showed the way for the scholar's vocation. The appeal offered a kind of corrective to unhistorical naïveté and crude, theoretically uninformed empiricism. In his early work Abel also sought to bring Weber's ideas into the orbit of American social science. Columbia provided a perfect setting for the cross-fertilization of these émigré perspectives with the work just emerging in the social sciences, encouraged by well-connected scholars like Robert Merton. One result of such convergence was the postwar seminars on the state and on bureaucracy that convened in 1946, attended by Merton, a newly arrived C. Wright Mills, Daniel Bell, S.M. Lipset, and others – a common forum for historians, sociologists, and political scientists. Minutes of the meetings show a striking reliance on shared knowledge of ideas central to Weber's work, then applied to the development of the modern state in a variety of circumstances, from the Soviet Union's efforts at economic development to the politics of decolonization in the developing world.

Stemming from these discussions, Merton's Reader in Bureaucracy (1952) illustrated one path of development for a new Weberian perspective: no longer disputations over the Weber thesis about ascetic salvation religions, or interpretation of basic concepts, but an application of useful ideas drawn from Weber's texts and extended to novel problems and new research domains. It was this fruitful problem-oriented approach, at times dominated by questions about 'modernization,' in which the ideas could be restated, applied, criticized, elaborated, extended, and renewed.

Postwar Weberians

The third critical event in the United States was the postwar institutionalization of Weber's thought in the canon of social theory, the promulgation of a body of thought that, along with Marx and Durkheim, had to be read and mastered. The record of translations points to the fact that ideas bearing Weber's imprimatur started to become widely circulated only in the 1950s. Considering the textual basis for this development, six publications were especially important:

- Hans Gerth and C. Wright Mills published *From Max Weber: Essays in Sociology* (1946), a student friendly compilation that included a dramatic and informative biographical sketch. It was the Weber reader others had wanted years earlier, now perfectly adapted to classroom use.
- Talcott Parsons published a translation of the first four chapters of *Economy and Society* as *The Theory of Social and Economic Organization* (1947), a project delayed by the war. He consulted a short version of the text written by Shils and von Schelting, and then revised and expanded work begun by H.M. Henderson in England. This was the only part of *Economy and Society* that Weber had prepared for publication shortly before his death. In selecting his own title rather than Weber's, Parsons announced his intention to appropriate Weber for a general theory of society. It was Weber the social theorist that became Parsons's avatar.
- Edward Shils (with assistance from Henry Finch) published *The Methodology of the Social Sciences* (1949), finally releasing for public scrutiny some of his decades-long quest to master Weber's philosophy of science in translation. He introduced readers to commentary on the 'ideal type' and a concept of 'value neutrality' in place of Weber's proposal for 'value freedom' (*Wertfreiheit*).
- Hans Gerth translated and published *The Religion of China* (1951), completing the first volume of Weber's *Collected Essays in the Sociology of Religion*.
- Gerth then teamed with Don Martindale to produce *Ancient Judaism* (1952), the third volume in the *Collected Essays*.
- Finally, Gerth and Martindale published *The Religion of India* (1958), the second volume in the *Collected Essays*.

Completing Weber's three-volume sociology of religion was a major accomplishment, although the original essays were published in translation out of sequence in five different books, a situation that has never been rectified, even though Parsons had warned early-on about the resulting confusion in understanding the structure of Weber's arguments. But Weber's larger comparative historical question – why did modern rational capitalism emerge only in the West? – now came into focus. No one could henceforth write about the sociology of religion or the emergence of modern capitalism without taking Weber's arguments into account.

Regardless of the vicissitudes of partial and piecemeal translations, by 1960 the Anglophone world had a substantial body of Weber's writings, now widely and inexpensively available to scholars, teachers, students, and the general public. At the end of the decade one last addition completed the major projects:

- Guenther Roth and Claus Wittich published *Economy and Society* (1968) in three volumes, the most problematic of unfinished manuscripts, but finally presenting the treatise that many have hailed as the major work of the twentieth century in sociology and social theory.

Having the complete text of *Economy and Society* available was important for establishing the domains of the sociological field of inquiry – the so-called special sociologies of religion,

law, economics, politics, culture, administration, associations, urban life, and so forth – as well as the conception of sociology itself. With the presumed magnum opus in hand, it became possible to conceptualize the Weberian intellectual world, to map its features and to argue about their definition and implications.

Since then there has been continuous expansion and refinement of the textual basis of the Weberian project, casting a much wider net for those interested in the work. There have been some noteworthy surprises: for instance, the presence of a 'structural' perspective in a study like *The Agrarian Sociology of Ancient Civilizations* (1976) that seemed to some to have affinities with neo-marxist class analysis and to confirm the insights of what has been called Weberian marxism. The text actually revealed a vocabulary Weber shared with Marx and many others in German political economy. In addition, the political commentary in Weber's essays on Russia seemed to anticipate subsequent twentieth-century development and illustrated an analytic approach to large-scale social change, if not precisely a theory of revolution. Or Weber's early writings on the stock and commodity exchanges, previously unknown outside specialist circles, demonstrated a hitherto hidden side of Weber as a political economist and economic sociologist concerned with macro-processes, micro-level choices, and their relationship in rule-governed markets. The long-term effect of these postwar retrievals has been a significant reshaping of the Weberian field of inquiry, an extension of the horizon and an expansion of interests into new and uncharted territory.

Homecoming and Renewal

The identification, translation, and analysis of Weber's writings starting in the 1950s, especially in intellectual circles in America, was important not only for the social science disciplines in the Anglophone world, but because the intellectual capital generated by this activity became the basis for the fourth major development in Weberian thought: the reintroduction of Weber's work in Germany, and its transnational renewal under changed circumstances.

While the growth of Weberian perspectives in America was the precondition for the work's return home in the 1960s, it was also the catalyst for the critical reassessment of Weber's contribution and its liberation from limiting preconceptions. The Weber who returned had been domesticated and appropriated by a Parsonian framework consistent with the behavioral revolution in the social sciences. The homecoming was thus laced with controversy, as the efforts in Germany to recover the work achieved public notoriety during the political struggles and academic debates of the 1960s. The abstracted version of Weberian sociology promoted by American scholars like Parsons and in a very different way, Reinhard Bendix, seemed to critics ill-suited to address the burning issues of the day. To be sure, Parsons had channeled Weber's ideas into the postulates of systems theory, structural functional analysis, and the explanation of modernization and social evolution, while Bendix had promoted historical sociology with a Weberian accent and emphasized Weber's appeal for empirical studies free from partisanship. Neither reconstruction was designed to address a looming political crisis. With the disputants talking past each other, the rationale for a distinctive Weberian approach was easily lost in a cacophony of opposing voices.

But the contentious decade of the 1960s turned out to be a prelude to the serious incorporation of Weber's work in the revisionist scholarship of the 1980s and afterward. In Germany evidence was provided by the major and quite different analyses of scholars like Wolfgang Mommsen, Jürgen Habermas, and Wilhelm Hennis. In the social sciences internationally Weberian ideas cast a long shadow over the critique of modernization theory and the work emerging in comparative historical sociology, political and economic sociology, and the investigation of the development of the modern state. These efforts were largely a transatlantic affair, though because of his international fame, the most noticeable contribution came from Habermas.

In his two-volume treatise, *The Theory of Communicative Action* (1984, 1987), Habermas returned to Parsons' theory of social action, which had been derived from a reading of Weber. But instead of accepting Parsons' formulation of Weber's social thought, Habermas set out to develop an ambitious critique of rationalism and rationalization processes. Most significantly, his understanding of the peculiar nature of rationalism in the West was based upon Weber's category of instrumental or purposive rationality (*Zweckrationalität*), that is, the kind of goal-oriented action that aims to maximize an efficient matching of means to ends. Working with Weber's category, he pushed the critique in different directions, arguing in essence that instrumental rationality had run amok in the modern world, invading the human world of everyday experience, violating the natural world, and threatening the very existence of humankind. This sobering analysis served as the platform upon which Habermas launched his lifelong effort to rescue enlightened reason and to find a way out of the cul-de-sac of a fully rationalized and disenchanted modernity.

Habermas' critique, supplemented by the work of others, exemplified an important new direction: for now in social theory Weber had became not the theorist of social action, or the origins of capitalism, but of the world–historical dynamic of rationalization. This was a potent invention. It mean that Weberian thought was linked to the most consequential problem of modern social theory: the radical differentiation and separation of the spheres of value – science, morality, art – and the dissociation or 'decoupling' of the human life–world from the social mechanisms of economic, administrative, and legal control. Weberian social theory now belonged to the Western philosophical tradition. It spoke to the most fundamental questions of the human condition.

Weberian Social Thought Today

The sustained critique of the initial uses of Weber's ideas was essential to liberating Weberian thought and making possible the notion of a distinctive Weberian perspective, approach, theory or 'paradigm.' Today Weberian approaches appear in widely dispersed domains of inquiry, from the significance of religion and the sacred to rational choice theory and formal modeling – so-called 'analytic Weberianism' (Kiser and Baer, 2005). Coherence amid such variety is provided by the sense

that the contemporary Weberian paradigm insists on an approach which is configurational, multicausal, multilevel, and committed to the idea that social and economic action is always embedded in social institutions and practices. It tends also to favor inquiries that are historical and comparative.

The other essential point to make about Weberian social theory is that, following Weber's lead, it is not confined to a single mode of explanation. That is, the advantage of Weberianism is that it can combine (1) macro-level structural analysis that pays attention to economic class and social status; (2) institutional analysis that investigates how and why rules of the game are devised and then constrain human action; (3) cultural analysis that inquires into the values, beliefs, and symbolic expressions which endow action with meaning; and (4) micro-level deployment of models of purposeful or instrumental rational action and its intended and unintended consequences. The choice of a particular mode of explanation depends not on methodological precepts, but on the research problem under investigation. From the Weberian perspective the questions asked take precedent over the toolkit of methods and determine the structuring of an inquiry.

However, today Weberian social thought is not confined only to academic specialties. It has migrated worldwide into the sphere of public opinion, political comment, and cultural interpretation. The problems of the new century have moved on, and Weber's thought has accompanied them. In this regard the thought has remained timely because of its problematic, the questions asked about the forces shaping our modern world. So long as such questions persist, Weberian thought promises to remain edifying, engaged, and capable of renewal.

Weight Regulation

Jane Wardle and Fiona Johnson, Cancer Research UK Health Behaviour Research Centre, University College London, London, UK

Abstract

Identifying processes underlying weight regulation in humans poses a challenge. Dramatic increases in body weight worldwide implicate environmental causes for the problem of obesity, but the high heritability of weight and striking interindividual differences in adiposity, even within similar environments, demonstrates genetic influence. One model that incorporates both environments and genes argues that genetic factors influence appetitive traits, which affect vulnerability to overeating in 'obesogenic' environments. Traditional approaches to supporting behavior change for weight regulation are often initially successful, but fail longer term. Strategies that take account of appetitive differences could help to assist with long-term maintenance of weight loss.

Weight regulation in humans is poorly understood. Most people's weights are relatively stable over days, months, and even years, despite considerable day-to-day variation in energy intake and dietary quality. On this basis, fat storage has been assumed to be under homeostatic control. However, defense against weight loss appears to more efficient than that against weight gain. Explanations for this imbalance have tended to focus on human evolutionary past (Prentice et al., 2008). The 'thrifty gene' hypothesis proposes that genes predisposing to energy storage survived into the modern human genome because they provided better survival and reproductive success over times of famine. Others have argued that there have also been pressures against weight gain, because higher body weight could increase the risk of predation. Either way, it is clear that although some people show little tendency toward weight gain and appear to need no deliberate effort to maintain a healthy weight, a tendency for progressive weight gain affects a substantial proportion of the population. Among those who show weight gain tendencies, some also find weight loss, and especially maintenance of weight loss, extremely difficult, and may reach very high levels of adiposity, resulting in the clinical problem of obesity. Hence, until recently clinical obesity was understood as a genetically influenced metabolic abnormality.

However, views about the etiology of obesity have been challenged by the dramatic rises in population weights and rates of obesity worldwide. Starting in the United States in the 1980s, population weights began to rise and the prevalence of obesity increased steadily across the globe (Finucane et al., 2011); now exceeding 90% in some Pacific nations, over 30% in the United States and the Middle East, and over 20% in Australia and many European countries. Even in the developing world where undernutrition is common, obesity rates are rising leading to a dual burden on health care services. This astonishing rise in a biological parameter that was once thought to be primarily under homeostatic control strongly implicates environmental, cultural, or social influences.

The 1950s saw a change of perspective on 'weight problems,' when the American Public Health Association declared obesity to be not just a matter of personal or aesthetic concern but a major health threat. This was on the basis of accumulating evidence of associations between obesity and a wide range of chronic diseases as well as reduced life expectancy. In 1997, the World Health Organization began a consultation that confirmed the gravity of the emerging global obesity crisis and called for investment into effective long-term treatment and preventive strategies. In the resulting report, the key role of behavior, for both prevention and treatment, was recognized (WHO, 2000). The growing obesity crisis highlighted the importance of understanding the process of weight regulation.

Increasing Population Weights: Environmental Factors

The worldwide increases in body weight, and the timing and geographic distribution of weight changes, strongly implicate modern lifestyles in upsetting the balance between energy intake and energy expenditure. Changes in transportation and mechanization have reduced the energy demands of everyday life, and combined with the growth in sedentary, screen-based entertainments, this has had the potential to greatly reduce activity-related energy expenditure. Substantial changes have also taken place in the food environment, with developments in food production, processing, storage, and preparation since the middle of the twentieth century, resulting in highly palatable and energy-dense foods becoming progressively more accessible, more strongly marketed, and cheaper. Whether lower energy expenditure or higher intake is the principal causal factor is debated, but either way it is clear that the modern environment has undermined the capacity of internal regulatory systems to match energy intakes with energy expenditure.

The change in obesity prevalence has also been linked with changes in its demographic distribution. Obesity was once more common among the wealthier groups in society, and in developing countries, the rising obesity rates are still seen primarily in the affluent, urban communities. But in affluent Western countries, the patterning has reversed, with obesity now being more common in people from lower socioeconomic status (SES) backgrounds (Shrewsbury and Wardle, 2008).

Although there is little doubt that changes in the food environment are important, less is known about which particular aspects are primarily responsible for promoting

overconsumption. If humans are, at least in part, opportunistic eaters, accessibility (e.g., availability, visibility or price) would be expected to play a role. Studies have shown that foods displayed prominently – for example, near the front of a food display – are more likely to be selected. In some countries, this evidence has led to supermarkets limiting displays of snack foods for children at the checkout, and to school meal services placing fruits and vegetables prominently on their displays to increase consumption. The sight and smell of highly palatable foods has a well-established influence on appetite. These responses may have a biological foundation in the need to meet future, as well as present, metabolic needs (Johnson, 2013). Food variety also influences consumption, partly at least through the phenomenon of sensory-specific satiety; allowing people to be sated for a particular food but retain an appetite for a different food (e.g., the appeal of dessert). Again this may be a biologically driven adaptation that once served to reduce the risk of micronutrient deficiencies associated with a limited dietary repertoire. External cues may also operate through influences on social norms. For example, the influence of portion sizes on consumption has been attributed to the supplied portion size giving an implicit social norm for the 'right' quantity to consume. This and other environmental influences may be outside consumer awareness (Vartanian et al., 2008), but are potentially modifiable aspects of the food environment, which could reduce the risk of overconsumption.

Individual Variation in Weight and Weight Regulation

The obesogenic food environment has not resulted in uniform increases in weight across the population. This could be partly due to differential exposure to the environment, but the fact that variation in weight is seen even within families who share the same home and local environment suggests that there are substantial individual differences in vulnerability to weight gain. In England, the slimmest 10% of the population in 2003 had a BMI very similar to the slimmest 10% in 1993, but the BMI increase in the top 10% was over 3.5 BMI units, and this pattern was the same in all socioeconomic groups (Wardle and Boniface, 2008). In fact, it is morbid obesity (BMI > 40) that has risen most dramatically, increasing by almost 50% in England in the decade between 2001 and 2011, and by 70% between 2000 and 2010 in the United States. These findings are consistent with the idea that it is the most genetically susceptible individuals who are most vulnerable to the obesogenic environment.

Both thinness and fatness are known to run in families; implicating genes not just in obesity but in the level of adiposity across the weight spectrum. Family studies cannot definitively distinguish shared genes from a shared home environment. However, adoption studies demonstrate elegantly that familial resemblance in weight maps onto biological, more than environmental, relatedness, with adopted children's weights showing no correlation with the weights of their adoptive parents (Stunkard et al., 1990). Twin designs provide a method of estimating of the relative balance of genetic and environmental influence in explaining variation in weight by comparing the extent of resemblance in genetically identical (MZ) and fraternal (DZ) twins. The typical finding in all the early twin studies was that upwards of 70% of the variation in weight could be attributed to genetic influence (Grilo and Pogue-Geile, 1991). Adoption studies have confirmed the same degree of resemblance in twins who are adopted apart as those who are reared together (Stunkard et al., 1990). One concern is that many of the large twin studies on weight were carried out before the 'obesity epidemic' gained traction, and so they may not reflect the impact of powerful environmental forces that tend to increase weight. However, in a large pediatric study of twins born after the onset of the obesity epidemic, the extent of genetic influence was as high or higher as it had been in earlier times (Wardle et al., 2008); implying that expression of obesity risk genes is not diminished by a 'permissive' food environment and may even be enhanced. Both gene–environment interactions (genetically mediated variation in susceptibility to environmental disruption of weight regulation) and gene–environment correlations (genetically mediated variation in the tendency to seek out obesogenic food environments) are thought to play a role in enhancing the toxicity of the obesogenic environment for genetically susceptible individuals.

The high heritability of weight raised hopes that it would be possible to identify the genes influencing weight. In 1997, the discovery of a mutation in the leptin gene in mice that was associated with leptin deficiency and severe, early onset obesity provided the first evidence for a specific obesity gene. The subsequent demonstration of a similar mutation in humans, followed by evidence that leptin replacement in a child with this mutation resulted in weight loss, had a profound influence on the understanding of the biological mechanisms underlying weight. However, the number of families carrying the leptin mutation proved to be small, and, therefore, this abnormality could not explain so-called 'common obesity.' Furthermore, leptin levels in most obese people are high rather than low. With the advent of genome-wide association studies, a common variant in the fat mass and obesity associated (*FTO*) gene was discovered to have a strong association with body fat from age 7 years upwards (Frayling et al., 2007); albeit with a much smaller effect than the leptin gene. The 16% of adults who are homozygous for the risk allele weigh about 3 kg more and have 1.7-fold increased odds of obesity compared with those not inheriting a risk allele. Since that time, many additional genetic variants have been discovered, and the current view is that there are hundreds of gene variants, each with a very small effect size, that underlie the heritability of weight. Individuals inheriting a lower number of high-risk variants would be expected to be thin, while those with a large number would – given an environment that makes it possible for them to get larger amounts of food – be overweight or obese. Generating a polygenic risk score based on the number of high-risk variants out of 32 of the single nucleotide polymorphisms identified to date, already shows a quantitative association with weight (Llewellyn et al., 2014). At present, the total variance in weight explained by known genes is still a fraction of the genetic influence identified in twin studies – a problem known as the 'missing heritability' – although recent analyses using the genome-wide complex trait analysis method show that molecular genetic influences are getting closer to the twin estimate.

Given the evidence that environmental factors influence weight at a population level, what evidence is there that the local environment of the individual is an important determinant of their weight status? The observation that there are strong – and possibly increasing – SES differences in weight is consistent with the idea that aspects of the home environment and local area are important. However, it is also possible that factors such as social norms for eating and weight or nutrition knowledge, are the primary mediators of SES differences; operating by modifying vulnerability to the external environment. There is some evidence that lower SES neighborhoods have more fast-food outlets, less availability of fruit and vegetables, and fewer pleasant green spaces for activity. However, although there has been a lot of interest in the idea that the local environment could play a role in determining the local prevalence of obesity, the findings have been inconsistent. Equally, there has been interest in the idea that the home environment plays an important role in setting children's weight trajectories. To date, comparisons of homes with more versus less availability and accessibility of energy-dense or healthy foods, have not found consistent associations with children's weights, but these studies have been dogged by measurement difficulties. Twin studies with large samples can also provide estimates of the shared environment effect. So far twin analyses indicate an effect of the home environment in the early years, but this dwindles to little or no effect by adulthood. Adoption studies also find that twins reared apart resemble each other as much as twins reared together by adult life (Stunkard et al., 1990); indicating that the long-term influences of the childhood home environment may not be as strong as is often hypothesized.

The fact that the most influential obesogenic environment effects appear to be broader than the home and the local neighborhood does not mean that environmental control is irrelevant. It is entirely appropriate for obesogenic exposures to be controlled and contained in settings for children (home, day care, school), and in health care settings (hospitals) and workplaces. Ultimately, control in multiple local environments could coalesce into a powerful broader force, especially with government support.

Appetitive Behavior as the Link between Genetic and Environmental Influence

One resolution to the paradox of weight being both highly heritable *and* under strong environmental influence is the idea that obesity risk genes do not 'cause' excess weight directly by effects on metabolism, but rather they influence susceptibility to environmental opportunities for overconsumption. In an environment with multiple attractive eating opportunities, people who are most responsive to food cues and least responsive to internal satiety cues will be most likely to overeat (Carnell and Wardle, 2008). According to this model, appetitive traits provide a potential intermediate behavioral phenotype linking genetic and environmental processes.

An appetitive model of obesity was first described in 1968, when Stanley Schachter published a seminal paper identifying common causes for obesity in humans and rats. He used the preload paradigm to examine adjustment of subsequent food intake in relation to the calorie content of a high-energy 'preload' (usually a milkshake or ice cream), and showed that obese adults (or rats) were less accurate at downregulating their appetite after a preload than normal weight individuals (Schachter, 1968). He also showed that obese adults were more responsive than normal weight adults to the palatability of food, increasing their intake relatively more when presented with highly palatable food. This model was the first to emphasize psychological factors – in this case responsiveness to internal and external cues – as key determinants of obesity. However, the model fell out of favor as attention turned to dietary restraint as an important influence on weight (see below).

There has now been renewed interest in appetitive traits as risk factors for obesity – reprising Schachter's model, and emphasizing interactions between the individual and the environment (Carnell and Wardle, 2008); driven in part by developments in our understanding of the genetics of obesity. Importantly, the model was extended to demonstrate that there are not only differences between the eating behavior of obese and normal weight individuals, but also that appetite is quantitatively related to weight across the weight distribution. Studies of children show a more or less linear association between weight status and both food responsiveness and sensitivity to feelings of fullness (satiety responsiveness).

The key finding was that 'obesity genes' influence appetitive processes. All monogenic forms of obesity identified to date are characterized by excessive appetite and diminished satiety. The first gene variant associated with weight in the general population, *FTO*, is highly expressed in the hypothalamus, an area of the brain linked with appetite, and expression of *FTO* is responsive to short-term variation in energy balance from underfeeding or overfeeding. Obesity-related gene variants also predict brain activity in response to food stimuli. The most direct evidence comes from human studies showing that *FTO* is related to satiety sensitivity, and that the effects are seen from early in life. Using a polygenic obesity risk score (described above), clear associations can be seen with satiety sensitivity, and there is evidence that satiety sensitivity may mediate the effect of obesity genes on weight (Llewellyn et al., 2014). These associations provide insight into the pathways that lead from genetic susceptibility, through behavior, to weight; and go some way toward explaining individual differences in weight regulation.

Deliberate Weight Control: The Dietary Restraint Story

Regardless of genetic and environmental influences, weight regulation is usually considered to be primarily the responsibility of the individual. However, messages on how weight can be controlled have often been confused and contradictory. Nowhere is this more apparent than in the longstanding debate over dietary restraint. The concept of dietary restraint was first outlined in 1975, describing an eating pattern consisting of attempted control over eating, but also characterized by regular failures of control. A raft of early studies showed that restrained eaters were less responsive to satiety, more responsive to palatability, and more likely to overeat in response to negative

affect; leading to the idea that chronic restraint itself led to loss of control over eating and a risk of subsequent weight gain (Herman, 1978); and to the adage 'dieting makes you fat.'

This was the era – the 1970s – when anorexia nervosa and bulimia nervosa were seen as the scourge of young women's psychological health, and when many women across the weight spectrum aspired to unhealthily low body weights. Psychological research on appetite and weight regulation in obesity dwindled, and the focus moved to strategies to improve body image and constrain efforts at weight control in young women. However, whether by virtue of the campaigns to improve body image or for other reasons, there were little or no further increases in rates of eating disorders, and the world of weight research was taken over by the dramatic rise in obesity prevalence that began in the late 1980s in affluent Western countries, and over the next 20 years in the developing world. The idea that this was all a reaction to excess dieting lost all plausibility – not least because the rise in obesity was equally strong in men (who certainly do not have the same body image issues as women) and women, and is emerging in countries and cultures where there is no 'slim ideal' as much as those that worship slimness.

One of the problems with the early studies on dietary restraint was that they could not exclude the possibility that a tendency toward overeating was the original trigger for the individual to try to restrict their food intake; which could explain why dietary restraint was associated with loss of control. The first psychometric measures of dietary restraint did not distinguish between the attempt to control eating (now often called restrained eating) and failures of control (called counterregulation or disinhibition), although later approaches to measuring restraint have acknowledged that the two behavioral tendencies are distinct, albeit often cooccurring (Johnson et al., 2012).

Restraint theory offered several models to explain the observed link between restraint and failures of control. The cognitive model proposed that after a high-calorie preload (in the laboratory) or after a dieting transgression (in everyday life), the dieter 'reasons' that they might as well take advantage of the situation and leave dieting until tomorrow. The psychobiological model suggested that dietary restraint interferes directly with an individual's capacity to respond to internal and external cues that influence food consumption. The emotional model suggests that the dieter copes with negative emotional states with dissociation, and as part of this, loses contact with their restrictive intentions.

Despite all these 'explanations' for why restrained eating may be ineffective, the body of clinical research suggests that restraint is actually associated with *less* overeating and *reduced* weight in the long term, and with better weight maintenance (Johnson et al., 2012). Increases in restraint are associated with better treatment outcomes, and formerly overweight individuals who have maintained a significant long-term weight loss tend to show increases, rather than reductions in restraint (Wing and Phelan, 2005). Nonetheless, it is also clear that restraint is difficult, and it is more than plausible that attempts at deliberate restraint trigger biological and psychological processes that tend to oppose weight loss. The key question may therefore be how to help people to exert effective dietary restraint in their daily lives.

Body Weight Perception and Weight Control

Provision of information and advice has been a key element of public-health attempts to address rises in obesity, under the assumption that recognition of unhealthy body weight is one of the prerequisites (although not a sufficient condition) for weight regulation in those with a tendency to gain weight. Several studies have shown that perceived weight status is a better predictor of efforts at weight control than actual weight status. However, promoting recognition of the need for weight control among the overweight and obese population is a conflicted area because raising awareness of overweight could have adverse effects on body image. The dominant discourse in the area of body image has been around normal weight women having excessive concerns about their body weight, and the need to ensure that young women – regardless of body size – grow up with a positive body image. However, recent studies have shown that perceptions of what constitutes a healthy weight are diverging from clinical guidelines, with increasing acceptance and normalization of overweight in all age groups. Many overweight and obese adults are unaware that they are carrying excess weight or that there is a need for weight control and underestimation of body size is increasing (e.g., Burke et al., 2010). Lack of parental awareness of overweight in children has similarly been highlighted as a barrier to healthy lifestyle change at the family level (Parry et al., 2008). Several explanations for inaccurate weight perceptions have been suggested. People are strongly influenced by prevailing norms of appearance and behavior, and the increases in population weights in recent decades may have 'upsized' perceptions of what constitutes a 'normal' body weight. Media coverage of the 'obesity epidemic' is often illustrated with images of extreme obesity (Patterson and Hilton, 2013), which may decrease recognition of more common levels of overweight and obesity. To tackling the growing problem of weight misperception, doctors in the United Kingdom are being increasingly encouraged to assess their patients' BMI and give advice on the need for weight control, and the National Child Measurement Programme is providing feedback to parents about their child's BMI. Accurate understanding of weight-related health risk may be a first step toward encouraging lifestyle changes to counter further weight gain.

Supporting Behavior Change for Weight Control

There is general agreement that simply providing education and advice regarding the components of a healthy diet and the desirable levels of physical activity has limited efficacy as a weight control strategy. Most obese people are broadly aware of the main components of a healthy diet and which foods are high in fat and sugar, although their detailed knowledge may be limited and they may misjudge their own diet quality. They are also aware of the importance of physical activity, even though they may overestimate their activity level. Many – at least at the higher weight levels – are also concerned about their weight; sometimes for health reasons and sometimes for appearance. The success of the commercial weight loss 'industry' and the popularity of books, television programs,

and Web sites on the topic of weight loss, all indicate that public motivation to lose weight is high.

For obese individuals seeking expert assistance with weight control, cognitive behavioral treatment (CBT) has been seen as the 'gold standard.' In essence, it aims to provide people with the skills to control their tendencies toward overeating and to adhere to recommendations for healthy eating and physical activity. It has been aligned particularly with achieving a permanent shift in behavior, and with modest weight loss goals; in contrast to drug treatments or surgery. The key elements of behavioral treatment are 'stimulus control' (reducing exposure to cues for eating, limiting the number of places in which eating occurs), alongside the standard behavioral procedures of self-monitoring, goal setting, and self-reinforcement. The cognitive elements include strategies to modify self-defeating cognitions and address the cognitions that contribute to the lapse–relapse sequence. CBT continues to produce positive results (Van Dorsten and Lindley, 2011).

As CBT principles have become more established and more widely disseminated, many dietary treatments include a behavioral element in parallel with a range of diet or exercise recommendations, including commercial programs such as Weightwatchers. The role of psychologists has largely moved away from delivering obesity treatment to providing advice and training to the wide range of practitioners who can deliver it at lower cost and on a larger scale.

Although the majority of overweight and obese people can achieve significant weight loss with a range of diet and exercise regimens, a much greater challenge is to sustain change over the long term. Long-term weight losers need to adhere to their dietary plans and stay highly active; they need to monitor their weight assiduously, and take steps as soon a deviation occurs. Failure to adhere to planned lifestyle changes is a key factor leading to weight regain in the majority of those who succeed in losing weight (Pagoto and Appelhans, 2013). Part of the difficulty is biological in origin, because weight loss induces physiological changes, which predispose to weight regain. Total energy expenditure appears to be reduced to a greater extent than expected from the loss of body mass (Rosenbaum et al., 2008), and there is evidence for persistent changes in appetite and satiety hormones, and increased neural response to food cues in weight-reduced individuals (Sumithran and Proietto, 2013); factors that conspire to increase the challenge of maintaining changes in eating behavior.

In its early days, there was hope that the control strategies included in CBT programs would equip patients with skills that could be applied long term. In practice, once the active treatment phase of CBT is over, gradual weight regain usually begins. Among the suggestions for achieving longer-term weight control is continuing therapeutic support; consistent with the view that few chronic conditions are successfully treated with brief interventions. Recent results from the Look AHEAD study, which started with a highly restrictive phase followed by a long-term maintenance phase that incorporated behavioral support, showed significant long-term weight change (2014). One issue may be that the primary focus of this intervention was prevention of diabetes, and the differences in treatment goals or the types of participants might mean that effects would be different in treatments focusing primarily on weight. Also, many obese patients are permanently on the lookout for a new treatment that will give better results, so long-term treatment 'merely' to prevent regain is not necessarily an attractive offer.

There is growing interest in other dietary approaches, particularly the use of meal replacements with low or very low calorie diets, to achieve rapid weight loss. This is sometimes delivered in the context of behaviorally based support, as in the Look AHEAD study. The last decade has also seen the rise and fall of the Atkins diet, and regimens of interspersed days of strict restriction and unrestricted eating are now attracting attention. Regardless of the specific dietary goals, some of the core features of CBT, such as self-monitoring, goal setting, and stimulus control would in principle be useful adjuncts; but this has not been a key focus of behavioral research.

There is increasing interest in interventions that can be delivered without the need for specialist therapeutic skills. Many commercial programs are based broadly on CBT and can deliver effective programs without the superstructure costs associated with health systems (Jebb et al., 2011). Self-help versions of CBT programs have been developed, though not fully tested. Of particular interest is the possibility that Web-based services might be a highly cost-effective enhancement to purely self-help treatments (Hedman et al., 2012). Alternative platforms for the delivery of more automated weight management support are also gaining increasing interest. Internet and mobile applications provide the user with the opportunity for an interactive experience without drawing on the costly time of a therapist. Self-monitoring is an intervention component that lends itself well to 'e-health' approaches and which has been repeatedly shown to assist with adherence to lifestyle changes (Ramage et al., 2014). Monitoring and recording fluctuations in weight, eating, and physical activity can help ensure that deviations from desired patterns are noticed and can act as a spur to remedial action.

The Future

Our understanding of the pathways linking genes, environment, and behavior to weight regulation is moving on rapidly. It is now clear that many people who have difficulty with weight regulation are facing a double onslaught of biological and environmental pressures.

It is unlikely that the broader environment will change dramatically in the near future. Governments are reluctant to regulate in areas where public support is low, and it seems unlikely that there will be significant public support for making the food supply less accessible, less palatable, or less affordable. It also seems unlikely that in a market-driven economy, food companies will be motivated to work out ways of making a profit by selling less food. But there could be changes in consumer preferences and pressures that will make it worthwhile for industry to apply technical expertise to producing foods that please the palate, promote satiety, and meet preferences for good value, all the while helping consumers to eat within metabolic needs. Despite this, it seems almost certain that psychological ingenuity will be needed to help people find ways of circumventing their overeating tendencies and enable them to achieve energy balance.

The evidence from recent years that genetic risk for obesity is mediated through higher food responsiveness and lower responsiveness to satiety could guide research into interventions that control these underlying tendencies. Strategies such as careful portion control and slow eating are already used to circumvent poor satiety responsiveness, but there may be other opportunities. For example, strategies to control deployment of attention, used to date in the mental health field, could possibly contribute to helping people control high food responsiveness.

There are some novel behavioral approaches; one of which harnesses habit-formation principles. Habits are behaviors that are performed automatically in response to environmental cues. Most of the health-related literature focuses on how to break bad habits, but creating new 'good' habits could have a role, and in principle could make actions that are difficult to remember easier to perform. The key to habit formation is repetition in a consistent context. Once automatic, the behavior requires less conscious effort to maintain and is more resistant to change than intentional behaviors (Lally et al., 2008). This approach is being tested in a number of behavioral domains including weight control – where the focus is on creating new 'negative energy balance habits' that will be easy to keep up in the long term.

There has also been interest in the possibility of 'training' children or adults in self-regulation, with a focus on intermediate skills such as goal setting, self-monitoring, emotion regulation, and coping strategies. These have had some success in improving skills and self-efficacy, and bringing about positive weight changes (Johnson et al., 2012). There is evidence for a generalizing effect of self-regulation training, with enhancements in one area (e.g., adherence to a physical activity program) improving an individual's ability to self-regulate across the board. It has also been suggested that controlled and supported exposure to tempting situations might contribute to strengthening self-control (Papies et al., 2008). Whether interventions can harness this effect requires further investigation.

Greater genetic knowledge and understanding of the behavioral traits associated with genetic differences may allow more effective tailoring of interventions to the specific vulnerabilities of individuals, and as in other areas of medicine there is a push toward personalized treatment. In the case of obesity, achieving an energy deficit is required regardless of the specific underlying cause, but if genetic information could help highlight individual vulnerabilities, it could be a benefit to those seeking to make changes to their eating and activity behavior. Even more promising is the possibility that a genetic link to weight control advice would provide an element of personalization that might make the information more salient and enhance adherence. Information on genetic risk has also been identified with reduced sense of self-blame, and this could be of benefit to well-being with positive effects on weight control actions.

Abstract

In the social and behavioral sciences, 'welfare' is widely used in at least two distinctive ways: (1) as the complex of state practices and administrative developments known as the welfare state and (2) as the main income support programs for the poor in the United States that serve as the modern successors to the centuries-long tradition of poor relief. Neither is it possible to summarize the extensive scholarly treatments of these subjects in the space allotted here nor is it a simple task to trace the separate meanings of welfare or centuries of experience and ideas about poor relief and disentangle them from the complexities of welfare state development. Instead, we highlight how the politics of welfare policy have shaped how we think about welfare as a societal concern and trace the main contours of the scholarly debates influencing the wide variety of programmatic interventions that constitute welfare state policy in the industrialized West. We begin with a note on origins, when local concerns were paramount; examine key ideas shaping liberal, social democratic, and conservative responses to the emergence of welfare states in market societies; and conclude with a brief overview of some of the main challenges for theory and policy in the contemporary period as economic globalization and supranational organizations come to play much more of a role in shaping policy.

Origins

Welfare states are modern in origin. Historians point to heterogeneous antecedents dating as far back as the Roman Empire or the first poor law of Charlemagne in 779. In Europe, population growth and the transition from feudalism to capitalism in the fifteenth and sixteenth centuries led to alarming increases in vagrancy and beggary. Religious and political elites responded with the development of the first relief systems to deal with the increasing threats to civil order posed by the vagrant poor (Piven and Cloward, 1993 [1971]). Local leaders in England and France at this time sanctioned private charity in the form of almsgiving as a means of personal salvation. The rise of market economies disrupted centuries-old traditional relationships between lords and vassals and the uses of the land upon which the peasantry depended for subsistence (Polanyi, 1968 [1944]). The growth of manufacturing and the rise of commerce dislocated the manorial organization and created an urban proletariat increasingly mobile and vulnerable to cycles in trade and foreign competition (Webb and Webb, 1963 [1927]). Local charity was no longer effective in quelling disturbances of the poor who rose up in reaction to a bad harvest or the seizure of commonly held lands for private pasture. Monarchs and governments responded, as, for example, when King Francis I of France ordered parish leaders to register the poor and to provide for the 'impotent' among them. Similarly, in England, a series of legislative acts of Parliament in the 1530s during the reign of Henry VIII required local officials to register the poor and regulate their begging by issuing personal certificates authorizing them to do so, and to require local parishes to take care of their poor by establishing procedures for the collection and distribution of funds, thus taking control of almsgiving away from religious authorities and establishing secular authority over charity (Piven and Cloward, 1993 [1971]). According to de Schweinitz, the Act Concerning Punishment of Beggars and Vagabonds of 1531 "represented the beginning of definite assumption by government of responsibility for the care of persons in economic distress" (de Schweinitz, 1961 [1943]: p. 21).

In England and Wales, and later, Scotland, public authorities played an early and unusually large role in the production of social welfare. This was accomplished through an increasingly complex system of rules and regulations governing poor relief beginning with the Elizabethan Poor Law of 1601 and continuing in the establishment of a legal regime that dominated for the next nearly 350 years (de Schweinitz, 1961 [1943]). The major features of the 'old poor law' system erected between the sixteenth and eighteenth centuries were a far-flung local system of parish administration of the laws, compulsory poor rates levied on every parish, residency restrictions aimed at stemming the flow of vagrants by requiring the poor to settle in some particular parish as a condition of receiving aid (de Swaan, 1988), differential means of assistance based on distinctions between the deserving ('impotent') and undeserving or able-bodied poor (the 'idle' poor received nothing and were to be whipped through the public streets until they reformed their ways), and a system of two types of relief: (1) 'outdoor' relief, which was the norm and through which the poor were left to reside in their own homes and given a 'dole' of relief in the form of cash, clothing, and food and (2) 'indoor' relief, by which the poor were confined to local alms houses, or later, workhouses; the ill were admitted to hospitals; and the orphans were taken into orphanages. Legislation to significantly reform the old poor law regime was passed in 1834, following recommendations of a Royal Commission. The parish system was largely abolished and a centralized authority created to prevent the wide variation in practices that was a hallmark of the old poor law system; outdoor relief was banned and the building of workhouses for different types of paupers expanded.

It is only with the birth of the modern state in the intellectual ferment of the Enlightenment and the upheavals of the French Revolution that we get the first statements of a governmental obligation to provide for the general welfare

of 'the people.' For example, Thomas Paine's *Rights of Man* (1791–92) declared that, "Civil government does not consist in executions; but in making that provision for the instruction of youth, and the support of age, as to exclude, as much as possible, profligacy from the one, and despair from the other" (Paine, 1999 [1791]: p. 151). Paine proposed a scheme for progressive taxation to support an elaborate plan for state aid to the poor that included a pension system, public works projects for the chronically unemployed urban poor, and supplemental income to support marriage and birth. The French Constitution of 1793, influenced by Paine's ideas, guaranteed a 'right to subsistence' and income redistribution in the form of public relief and public schooling. The modern history of welfare as a concept, policy, and program is one of recurring conflicts between the idea of property rights at the heart of the capitalist mode of production, and assertions of rights to subsistence and human and communal well-being that have shaped the democratic project.

Later, in the waning decades of the nineteenth century, the first framework for anything like a "systematic social concern for the welfare of people who might otherwise lack the basic necessities required for effective functioning within their community" (Goodin and Mitchell, 2000: p. ix) emerged in Germany as state activity organized through a limited program for social insurance. Most scholars date the origins of the modern welfare state to Bismarck's reforms of the 1880s that introduced compulsory insurance against sickness, accidents, and old age (Briggs, 1961). These innovations were followed by similar developments in Sweden and England, and eventually, in the United States with the passage of the Social Security Act of 1935 (Heclo, 1974).

Intellectual Background and Current Knowledge

Heclo notes that the 'welfare objective' of the modern state can take a number of forms, "… the most prominent being investment (e.g., education), consumption (public assistance payments), and compensation (industrial injuries)" (Heclo, 1974: p. 2). Similarly, Briggs argues that the welfare state is one in which organized power is used to insulate individuals and families from the play of market forces through guarantees of minimum income and insurance against the inability to participate in a labor market due to sickness, disability, and old age. The idea of insurance and the use of insurance principles in modern social policy helped to remove the stigma of pauperism and provided a bridge between voluntary methods of self-help and mutual aid and compulsory approaches to social provision that entailed and accompanied the massive growth of governmental intervention in the economy during the middle period of the twentieth century. Significant to the post–World War II development of the welfare state is the expansion of state income support programs from older legacies of relief to income support by right.

The social democratic analysts of the interwar and postwar welfare states provided an influential interpretation and rationale in defense of governmental protection against market failure and public provision of minimum standards of social well-being. Among them, T.H. Marshall's work stands out in shaping ideas about social citizenship, informed by egalitarian ideas about what he called 'social rights.' In a 1950 essay titled 'Citizenship and Social Class,' Marshall argued that rights had evolved from civil rights won in the eighteenth century, such as those necessary for individual freedom (i.e., freedom of speech, the right to own property, and the right to justice), to political rights, including the right to vote won in the nineteenth century, to social rights, a new concept which Marshall defined as "… the right to a modicum of economic welfare and security … the right to share to the full in the social heritage and live the life of a civilized being according to the standards prevailing in the society. The institutions most closely connected with it are the educational system and the social services …" (Marshall, 1950: p. 11). Social rights promised new claims to a standard of life and to 'full membership of a community,' by which Marshall meant equal citizenship (Marshall, 1950: p. 28). Social rights are contiguous with civil and political rights in that they are necessary for the full realization of those rights, but also 'at war' with market principles legitimated by such rights. In other words, they justify governmental regulation of markets as they legitimize welfare policies to expand services in order to ensure that all citizens have the capacities required for full participation and membership in the community. Marshall believed that as the welfare state expanded, social rights ultimately would defeat the divisions of social class.

Marshall's concept of a war between citizenship and social class appears to have been derived from Karl Polanyi's ideas about fundamental contradictions in laissez–faire capitalism and its drive to commodify labor power (Holmwood, 2000). In *The Great Transformation*, Polanyi argued that the premise of a universal psychology of utility maximization and self-interest undergirding the idea of a 'self-regulating' market was a myth, and its invention in both theory and practice a unique, historically specific development that emerged in England in the seventeenth and eighteenth centuries. For Polanyi, a market economy "is an economic system, controlled, regulated and directed by markets alone …" and, "self-regulation implies that all production is for sale on the market and that all incomes derive from such sales. Accordingly, there are markets for all elements of industry, not only goods (always including services) but also for labor, land and money, their prices being called respectively commodity prices, wages, rent and interest" (Polanyi, 1968 [1944]: pp. 68–69). Land, labor, and money were 'fictitious commodities' because they could be subjected to market processes only by denying their social substance outside the constraints of the commodity form. Thus, the problem with the self-regulating market is not a problem with economies or markets *writ large*, as all human societies have economies and markets developed in both premodern and modern economies, which did not limit human survival to market relations. Polanyi's critique of liberal political economy is that the idea that everything can be commodified, including human labor, was antisociety and a dangerous fiction, and by embedding social relations in the economy rather than the other way around, as occurs in other human societies, market economies sow the seeds of their own destruction.

Thus, "the variability of welfare state evolution," writes Esping-Andersen, "reflects competing responses to pressures for de-commodification" (Esping-Andersen, 1990: p. 37). In *The Three Worlds of Welfare Capitalism* (1990), Esping-Andersen advanced the study of welfare states by first rejecting the call

of classical political economists for universal laws in understanding the social and political world. This had led to the misspecification of welfare states based on a misplaced presumption that as states experienced industrialization, urbanization, and modernization they would converge toward welfare state status. For classical theorists, the measure of a welfare state was its level of expenditure on services addressing human needs outside the cash nexus of a market economy. Instead, Esping-Andersen argues that "the welfare state cannot be understood just in terms of the rights it grants …" (Esping-Andersen, 1990: p. 21), and that "expenditures are epiphenomenal to the theoretical substance of welfare states" (Esping-Andersen, 1990: p. 19).

His influential approach offers a more flexible comparative methodology, sorting welfare states into different regime-type clusters based on social democratic, corporatist, and liberal or residual forms of state intervention. The different types of welfare state regime vary across a set of conditions that include (1) the degree to which a welfare state has reached decommodification (which "… occurs when a service is rendered as a matter of right, and when a person can maintain a livelihood without reliance on the market" (Esping-Andersen, 1990: p. 22)); (2) the impact of welfare state programs on social stratification, for "the welfare state is not just a mechanism that intervenes in, and possibly corrects, the structure of inequality; it is, in its own right, a system of stratification … [and] an active force in the ordering of social relations" (Esping-Andersen, 1990: p. 23); and (3) the particular blend of private and public welfare provision reflecting peculiar state–market relations. Here, Esping-Andersen argues, "The division of social protection between public and private provides the structural context of de-commodification, social rights, and the stratificational nexus of welfare-state regimes" (Esping-Andersen, 1990: p. 80).

Welfare states are classified beyond mere effort or generosity in redistribution to take account of their impact on social structure. Corporatist welfare states such as Germany and France have as a goal the preservation of a social order, with paternalistic programs and a larger role for religion in society. Liberal welfare states emerge from classical liberalism's war against traditional social hierarchies and celebration of the free market. Thus, liberal social welfare states such as those in the Anglo-American orbit encourage more interaction with the labor market for purposes of income maintenance and insurance against risk. Finally, social democratic welfare states, built by the efforts of strong labor movements to construct the basis for social solidarity, favor universalism in program design to link policies to a broader goal of social citizenship. Sweden and the Nordic welfare states represent this model.

Myrdal (1944) and Titmuss (1974) had expressed similar ideas about stages of welfare state development. For example, Myrdal writes, "Social reform policies may be conceived of as passing through three stages: a paternalistic conservative era, when curing the worst ills is enough; a liberal era, when safeguarding against inequalities through polling the risks is enough; and a social democratic era, when preventing the ills is attempted" (Myrdal, 1944: p. 152). But welfare capitalism and welfare regime ideas helped to broaden the concept of the welfare state beyond the traditional focus on the transfer sector of the capitalist economy to a larger set of concerns about a wider range of values, socioeconomic institutions, policies, and programs all oriented toward promoting human welfare. Esping-Andersen's work sparked a debate about the variety of national experiences and the preeminence of labor market formations and labor power decommodification as defining of the most significant differences among welfare states. Some claim that he misspecifies the Mediterranean welfare states, others reassess his methodology, and feminist critiques address his neglect of unpaid work (e.g., Arts and Gelissen, 2002; Lewis, 1992; Orloff, 1993; Scruggs and Allan, 2008).

Other lines of research and theorizing about welfare expanded in the 1980s and the 1990s. Of growing importance were analyses that centered on the politics of the welfare state. Piven and Cloward's groundbreaking work on the functions of public welfare (*Regulating the Poor*, 1993 [1971]) presented a theory that reconceptualized the entire history of relief giving in terms of its uses by elites in the larger economic and political order. Rather than a progressive unfolding of a modernizing state apparatus concerned with conferring social rights or promoting human welfare in the face of market instabilities, the history of relief giving for Piven and Cloward was one of expansion and contraction in response to labor conditions among the lower classes. They drew from the rich historical record of peasant uprisings and food riots, factory revolts and occupations, violent opposition to land seizures, vagrancy, and patterns of crime to show how popular resistance to the dislocations of capitalism in effect created the welfare state and shaped the specific forms it took, especially in the United States.

Their controversial thesis stimulated an enormous body of work dealing with questions about the origins of the welfare state, the political process through which policies to deal with poverty are initiated and sustained, the role of parties and interest groups, unions and reform organizations and the institutions that shape them, and the relationship of class mobilization to labor decommodification, among many other topics. Their prescient insights into the importance of conflict to welfare state development and their explicitly political analysis of relief giving have come into even sharper focus with the rise of neoliberalism, the New Right, and policies of welfare state retrenchment in the current period. Before we turn to those important developments, a discussion of the US case is in order.

The US Context

Esping-Andersen characterizes the United States as a 'liberal' welfare state, where "… the state encourages the market, either passively – by guaranteeing only a minimum – or actively – by subsidizing private welfare schemes" (Esping-Andersen, 1990: pp. 26–27). As such, people in the United States typically think of 'welfare' as means-tested government-provided cash assistance, only available to those with incomes below a specified level, although the term also includes social insurance programs such as social security, disability payments, and unemployment compensation. The latter are not means-tested programs and do not carry the same kind or degree of stigma as they represent earned benefits rather than 'relief' (Gordon, 1994; Jansson, 2001; Katz, 1986).

What people usually think of as 'welfare' was born as a federal program as part of the New Deal, but that was not the beginning of assistance provision for poor women and children (Katz, 1986; Teles, 1996). In 1935, the Social Security Act, which contained Aid to Dependent Children (ADC), supplanted what had thus far been state-based mothers' aid programs, usually called widows' pensions or mothers' pensions, perhaps the real beginning of modern welfare (Jansson, 2001; Katz, 1989; Teles, 1996). Those mothers' pension programs originated earlier in the twentieth century (and their roots extend much farther back; see Handler and Hasenfeld, 1997; Katz, 1986) and were designed to provide for widows; most single mothers at the time were widows rather than those who had children outside of marriage, were divorced, or were abandoned by their husbands. Most states developed mothers' pension programs between 1911 and 1919, and nearly all states had them by 1934, but relatively few women received actual benefits; the programs were generally miserly and restrictive. ADC was a federal version of mothers' pension programs, although eligibility standards, grant levels, and other specifics of implementation were left to individual states. ADC provided funds to families with a single parent, and funds only for the children and not for the parent. In 1939, amendments to the Social Security Act extended Old Age Insurance to the widows and children of deceased workers, so a group of those eligible for ADC were now covered by an insurance program and the 'relief' program came to be more for the 'unworthy.' The change meant higher benefits and better treatment for widows and lower benefits and punitive treatment for unwed mothers. Insurance was a benefit program, whereas welfare was a relief program. As mothers' aid or widows' pensions became ADC, some sympathy might have been extended to all ADC recipients, but once ADC recipients no longer included widows, public sympathy for them disappeared (see Katz, 1986; Teles, 1996, for comprehensive treatments).

For the next three decades, ADC remained a program restricted, for all practical purposes, to white women (Gordon, 1994; Neubeck and Cazenave, 2001). The program was renamed Aid to Families with Dependent Children (AFDC) in 1962, and the policy limiting funds to children was amended (Handler and Hasenfeld, 1997; Jansson, 2001; Teles, 1996). The National Welfare Rights Movement, and several court cases and amendments from 1939 through the 1970s, succeeded in expanding the program to all those who qualified financially, regardless of race, and the welfare rolls grew (Gordon, 1994; Handler and Hasenfeld, 1997).

Welfare receipt carries a strong stigma in the United States (Abramovitz, 2000; Edelman, 2012; Ellwood, 1988; Gans, 1995; Gilens, 1999; Gordon, 1994; Hays, 2003; Katz, 1983; Piven, 1996; Piven and Cloward, 1993 [1971]; Rogers-Dillon and Skrentny, 1999; Schram, 1995; Teles, 1996). People tend to blame the persistence of poverty on poor individuals (Handler and Hasenfeld, 1997; Katz, 1983). The emphasis on individual responsibility and material success as a barometer of moral worth necessitates an antipathy toward welfare and those who receive it. Popular American images of people on welfare depict recipients' problems as their own fault (Katz, 1983). Politicians have stirred public outrage about welfare and welfare recipients "with images of steaks in welfare freezers and Cadillacs in the parking lots of public housing" (Katz, 1986: p. 278). The 'welfare queen' image, popularized by Ronald Reagan, is based on myths about women defrauding and abusing the welfare system to become wealthy (Zucchino, 1997).

Much of this welfare stigma is shaped by racial stereotypes (Gans, 1995; Gilens, 1999; Quadagno, 1994; Zucchino, 1997). The white American public generally thinks that most recipients are black (although this is untrue; see, e.g., Hays, 2003), and that blacks are less committed to the work ethic than are members of other groups. Racial stereotypes of blacks as lazy and biased media coverage play a role in generating opposition to welfare (Gilens, 1999). The feminization of poverty and American images and ideas about poor women also depress public support for welfare (Abramovitz, 2000). Poor women, especially single mothers, confront conflicting pressures; they are expected to be providers, working in the paid labor force, and to be the sole caretakers and nurturers of their children.

Six decades after the creation of ADC, The Personal Responsibility and Work Opportunity Reconciliation Act (PRWORA) of 1996 replaced the federal entitlement program for low-income families, AFDC, with a state-administered block grant program, Temporary Assistance for Needy Families (TANF) (Moffitt and Ver Ploeg, 1999). PRWORA initiated cuts in assistance, restrictions on eligibility, time limits on receipt of assistance, and work requirements (Handler and Hasenfeld, 1997; Piven, 1996; Quint et al., 1999). PRWORA fundamentally changed welfare from an entitlement available to all who qualify financially to a punishingly restrictive program. Until that time, the typical welfare recipient was already only on welfare for less than 2 years, due in part to the strong pull factor of work in generating positive self-esteem and regard from others (Bane and Ellwood, 1994; Edin and Lein, 1997). At the implementation of welfare reform, a time of economic boom and lower unemployment, the welfare rolls were already falling. And in the 5 years after PRWORA, the number of welfare recipients declined by more than half (Hays, 2003).

By a decade and a half after PRWORA, the percentage of the populace receiving welfare, in the form of cash assistance, remained very low, although the percentage receiving food stamps (the Supplemental Nutrition Assistance Program) ballooned during the 2007–09 recession and beyond, in a time of high poverty and unemployment. In 2010, the number on TANF was about 4.5 million, while the number receiving food stamps was 10 times that – close to 46 million in 2011 (Edelman, 2012; United States Department of Agriculture, 2013; United States Department of Health & Human Services, 2013). There remains a right to receive food stamps, while the right to receive welfare has been virtually eliminated. The low rate of welfare receipt does not reflect lower rates of need, but rather a more limited public safety net of 'welfare' (Edelman, 2012; Hays, 2003).

Conservative Critiques and Welfare Retrenchment

There are many ironies in the contemporary neoliberal assault on welfare state programs, not the least of which is conservatism's characteristic defense of the past. A hallmark of older

European conservative ideologies is the notion that the commodification of human beings is morally degrading and that individuals are not meant to compete with one another but rather subordinate their self-interest to traditional sources of authority (Esping-Andersen, 1990: p. 40). Elites generally feared the march of liberalism, capitalism, and democracy as threatening to their traditional sources of authority and prestige. Feudal notions of the obeisance owed the lord included norms of reciprocity and noblesse oblige owed the peasant. A market-set wage was not the final word on the value of a laborer's contribution when his house burned down or he suffered the loss of a child. In our own time, patronage and clientelism, guilds and fraternal associations, mutual aid societies, and all manner of private charitable giving meant to inspire loyalty, social integration, and the preservation of authority also reflect a disdain toward the commodification and atomization of the individual.

Attacks on public provision of welfare are not new; they date back to the emergence of capitalist forms of production and the earliest relief efforts of the sixteenth century. And at every stage of development, with each new legislative initiative to deal with vagrant paupers, the ill, the infirmed, the aged, widows and children left destitute by the loss of a breadwinner, workers thrown out of work by mechanization, market downturns, and disinvestment, critics of government intervention to buffer or ameliorate these conditions resurrected older arguments about how relief programs were not good for society and worse for the poor themselves.

In the contemporary period, however, the substance of conservative critiques of welfare has little in common with older traditions. Today's conservatives generally favor markets over the state as superior mechanisms for the distribution of all goods and services produced in a society (Friedman, 1962; Hayek, 1960, 1976). Instead of a concern for tradition and the reciprocity of cross-class obligations in society, they claim the values of individual 'freedom' and 'choice' that markets promise to deliver upon. The main arguments are that (1) welfare spending is a drag on productivity and efficiency in the economy; (2) government supports for a social wage deter labor market participation because they provide tantalizing alternatives to work; and (3) both of the main forms of welfare state provision, social assistance and social insurance, have perverse effects on the broader economy, causing the very problems of 'dependency,' poverty, and a lack of class mobility that they are supposed to cure (Anderson, 1978; Gallaway and Vedder, 1986; Gilder, 1981; Mead, 1986; Murray, 1984; Novak et al., 1987).

These ideas were given powerful support with the rise of the New Right in the early 1980s, and especially, in the coming to national power of conservative probusiness, 'free market' regimes in Britain and the United States, where welfare 'reform' has resulted in the dismantling of the main means-tested income maintenance program for the poor, as noted above. Scholars debate the degree to which governments in the advanced industrial and postindustrial countries have retrenched in their provision of the broad mix of welfare state programs developed since 1945, such as old age pensions, unemployment insurance, income maintenance, child and family allowances, and the like. Paul Pierson's influential work on the 'new politics of the welfare state' (Pierson, 1994, 1996, 2001) argues that despite large-scale budgetary pressures, retrenchment has been limited by the strength of public opinion and support for core programs, and because the dynamics of policy 'feedback' or legacies create institutional hurdles to radical change.

It remains to be seen whether these arguments will withstand the effects of the Great Recession, and in particular, the imposition of austerity regimes in the Eurozone. Scholars will continue to debate the extent to which globalization, national integration and regionalization, deindustrialization, and post-industrialization have caused or will cause welfare state retrenchment in the advanced economies (e.g., Castles, 2004; Clayton and Pontusson, 1998; Huber and Stephens, 2001; Lindert, 2004; Scharpf, 1996; Scruggs and Allan, 2008; Swank, 2002, 2005). Meanwhile, developments in the emerging economies of the global South also demand attention. In many developing countries, both centrist and left-leaning governments have answered decades-long popular mobilizations among the lower classes with expansive social policy initiatives known as Conditional Cash Transfers (or CCTs), which tend to take different forms than the main programs of the Western welfare state and older types of poor relief. The programs are flexible in design, but all transfer resources to poor households, usually to mothers, on the condition that parents take active measures to build up the human capital of their children, usually by ensuring that their children are enrolled in and are attending school, and making regular visits to health care providers. Already, CCTs are having positive effects on poverty alleviation (Fiszbein and Schady, 2009). The erosion of the Western welfare state and the emergence of new forms of social protection in the global South present important questions for theory, research, policy, and practice in the forms of social provision we call welfare.

Abstract

The first section examines the entrenchment of educational policy in the tradition of three social welfare policies. These three basic concepts that help guarantee social welfare services each attach a specific value to educational policy.

The second section presents the international results of educational policy in three 'welfare regimes.' The particular political structures contained within are confronted with 'educational outcomes,' i.e., educational quality and equity.

The third section transfers this comparative approach to countries with emerging welfare policies in Latin America. The particular focus of educational policy and integration into the country's social policy determines educational quality and the level of equity.

The Relationship between Social and Educational Policy in Various Welfare Regimes

The educational level of each member of the society is not only relevant on an individual level, but also of great social importance, especially in modern complex industrialized societies. The level of education achieved is primarily significant for the position an individual will have on the labor market, while also having crucial secondary effects upon other important societal issues such as health status throughout the life course and general social capital (Levy and Murnane, 2003). Increased knowledge and enhanced skills ensure a higher chance of attaining an influential, well-paid, and secure position in the workforce, which stands in stark contrast to cases where only lower qualifications have been attained. Education is also one of the most important drivers behind the economic growth of a nation by enhancing general productivity; in addition, the consequences of limited education and insufficient qualifications after leaving school severely limits access to the job market, and in worst-case scenarios may result in downright exclusion. In this respect, the education of all individuals is one of the essential factors in the creation and maintenance of the social status and thus also of the quality of life of all members within the society. In summary, education is fundamental for development, for achieving a cohesive society, for reducing social inequalities, for combating social exclusion, and for combating poverty. Therefore, collectively, education also determines the economic and social prosperity of an entire country (Wößmann and Schütz, 2006).

Policy Traditions in Welfare States: The Role of Education

Consequently, it is all the more surprising that in the light of these correlations only little importance has been attached to educational policy within the political traditions of internationally comparative classifications. The differentiation of various clusters of social welfare policy is based first and foremost on a country's social policy, which in turn is primarily understood as being part of social security policy. A prominent example of this is the typology developed by Esping-Andersen in the 1990s. This approach defines a welfare state as a state whose policies structure both the society, as well as its social and economic relationships. It primarily sees the state in relation to the market and the family structures, and asks how state activities are interlocked with these two institutions in shaping social conditions and providing social welfare benefits. Education is not considered as a relevant component.

Esping-Andersen's classification distinguishes between three 'ideal types' of welfare state regimes (Table 1): The Anglo-Saxon 'liberal' welfare states (i.e., the United States, Canada, and Australia) emphasize the importance of market forces and offer only modest and means-tested benefits. The Central European 'conservative' welfare states (i.e., Germany, France, Italy, Austria, and the Netherlands) link the provision of social security to status differences and traditional family models. The Nordic 'social democratic' welfare states grant social security on the basis of individual social rights and direct their social policies toward achieving more equality, both in the public and private sphere.

As established by Esping-Andersen, welfare regimes could, but do not necessarily need to, include welfare states.

Table 1 Typology of welfare state regimes in developed countries

Welfare state regime types	*Characteristics*
Social democratic (Denmark, Sweden, Norway, Finland, and the Netherlands)	Welfare provision is characterized by universal and comparatively generous benefits; a commitment to full employment and income protection; a strongly interventionist state promotes equality through a redistributive social security system
Conservative (Austria, Belgium, Germany, and France)	'Status differentiating' welfare programs: Benefits are earnings related, administered through the employer, and geared toward maintaining existing social patterns. The role of the family is emphasized and the redistributive capacity is minimal.
Liberal (Canada, Great Britain, and USA)	The state provides minimal welfare benefits. Benefits are modest and often attract strict entitlement criteria, and recipients are usually indigent and stigmatized.

Esping-Andersen, G., 1990. The Three Worlds of Welfare Capitalism, vol. 6. Polity press, Cambridge.

Understood as constellations of practices that reallocate resources, welfare regimes may or may not include a well-developed public policy component. Consequently, the study of welfare regimes sheds light on the redistribution of resources, whether or not such redistribution is state-led. If labor markets are well organized and able to absorb the labor force, the less the state will play a role in redistribution, and the more dependent on markets and primary distribution the population will become. Yet when labor markets are highly informal and lead to large inequalities in income, nonmarket-based practices, such as family and community ties, expectations, and obligations, become more significant. Based on Esping-Andersen's work and adapted to Latin America, different authors (considering commodification, decommodification, and defamiliaritzation dimensions) have identified three regional patterns or welfare regimes: Productivist, Protectionist, and Familiarist. In these regimes, states do not necessarily play the same central role in defining welfare regimes as in the developed world; however, they do share some characteristics.

Welfare regimes in Latin American countries exhibit variation in their social policies, for example, in the type, combination, and measure of assistance and benefits they provide. The combination of their social provisions bears important consequences for the socioeconomic opportunities and outcomes of individuals and groups. For example, rapid development in the region has contributed to the erosion of absolute poverty but has simultaneously heightened insecurity and vulnerability. A good system of social policy helps people throughout their life cycle, protecting their first steps, ensuring access to opportunities for education and jobs, covering their risks of disease and disability, and guaranteeing old age with dignity. The welfare policies of Latin American countries include some level of provision for education, health care, old-age pensions, provision of cash transfers, and other safety net provisions. One of the first priorities in these countries has been education policy. In general, Latin American countries spend more or less on education than do Organisation for Economic Co-operation and Development (OECD) countries on average; however, they differ in terms of what they spend the money on and their education learning outcomes. Spending does not necessarily guarantee higher quality; indeed, Latin American countries do not appear to secure the greatest possible value from what is spent.

In this as in most other internationally relevant typologies, education has hardly been taken into direct account. Thus, the significance of education with regard to modern welfare development is completely underestimated. Education has a significant impact not only on the general population's social and economic development, but also on its prospective opportunities and perspectives. This in turn shapes the individuals' future as a crucial resource for the quality of life and the opportunities of social participation. A country's educational policy is thus as integral and decisive for a 'social welfare regime' as its social security policies (hereinafter referred to as 'social policies') (Allmendinger and Leibfried, 2003).

The Combination of Educational and Social Policies in the Three Regimes

The three ideal-typical welfare regimes mentioned here differ with regard to the value they attach to educational policy. In a historical-comparative analysis, Hega and Hokenmaier (2002) outline the importance of education in the development of welfare state traditions. They come to a clear conclusion:

- The Central European, structurally conservative 'welfare regime,' as established, for example, in Germany, traditionally attaches a minor significance to the role of educational policy. The focus lies on historical structures rooted in the social conditions of life. The entire social welfare policy, i.e., the protection of the population's quality of life, is essentially geared to the stabilization of existing structures.
- The market-oriented Anglo-Saxon regime, as established, for example, in Britain, pursues a development approach and is traditionally inclined to extensively invest in the educational sector in order to enable individuals to attain a stronger position on the job market, which minimizes the amount of future social transfer payments required to cover possible risks.
- The Scandinavian regime, as established, for example, in Sweden, traditionally invests in both the education of the individual members of the society, as well as in their protection against possible risks in the course of their lives. This regime is intended to provide all citizens with the opportunity to develop their own potential, and at the same time guaranteeing a high quality of life.

The results achieved by these three different approaches are very clear: the Scandinavian, structurally social-democratic welfare states, invest in both the potential status of their citizens as well as in status maintenance. Consequently, the Scandinavian regime invests the largest amounts both in education as well as in social welfare. At the root of this approach is a model of societal and individual autonomy that aims to provide all citizens with the same publicly funded social security benefits.

The liberal Anglo-Saxon countries invest heavily in the development of their citizens' potential and thus mainly in education and less in social security. The philosophy of this approach is to provide favorable starting conditions, which in combination with the opportunity of good education support the general development of all citizens. The further development of their own chances now lies in the hands of each individual and no longer constitutes a state affair. As a result, social security spending is low.

In structurally conservative, family-oriented Central European countries, a third political variation is typical: Education expenditure as social investment for status acquisition is rather low. The state focuses on status maintenance by enabling its citizens to uphold the particular standard of life traditionally achieved by their family. Consequently, larger amounts are invested in social security than in education.

Current OECD statistics confirm these tendencies (OECD, 2010, 2011). In addition to a comparatively small public percentage, a considerable private segment is available. As a prototype of a social-democratic welfare state, Swedish investments are comparatively lower. However, this is exclusively due to the lower percentage of private education expenditure. When taking only public means into account, Sweden would hold the leading position. Comparing the three country prototypes,

Germany as a conservative welfare state would take the last place in terms of public expenditure on education. Sweden belongs to the leading group of nations with regard to public educational and social expenditures; the United States holds a middle position with regard to educational expenditure but finds itself on the outer margins with regard to social expenditure. Germany takes a higher position with regard to social expenditures but drops to the lower third with regard to education expenditure. The other countries that could be assigned to one of these three welfare regimes do not deviate very much from the patterns established.

Structures of the Various Educational Systems

The varying importance attributed to educational policy affects the structure of each country's educational system. Comparative research has identified a variety of structural aspects within educational systems relevant to educational outcomes (Hofman et al., 2004).

Hofman and colleagues suggest three aspects that characterize the institutional context of schools:

1. The effect of the manner in which public and private education is financed.
2. The administration of public and private education.
3. The institutional effects of school choice and community involvement.

Regarding the type of financing of public and private education, we can see that most education systems include a private and a public sector, but are still funded in different ways. In some countries, the state finances both public and private schools equally, and implements identical policies in these schools. However, there are still differences in quality between public and private education. Other countries combine equal funding and identical policies in public and private schools. Such countries provide opportunities within the public education system to establish or choose grant-supported private schools. The size of the private educational sector may vary widely depending on the amount received from public funds (grant support) and/or from direct financial contributions by parents, corporate donations, or inherited funds.

When we consider the administration of public and private education, we can see that in many countries autonomous school boards administer grant-supported private schools, while traditionally local authorities govern public schools. Consequently, public education depends on local government policy while private education functions more autonomously.

This directly ties into the effect of choice and community involvement in public and private education since many studies trace the discrepancies between public and private schools to environmental differences and their internal social systems. Parental involvement in school affairs (e.g., school choice; parental involvement in schoolwork and in school life, as well as influence on school board decisions) reflects positively on academic performances. Both public and private schools are subject to administrative bureaucratic control, whereas public schools – dependent on government bureaucracy – must submit to extensive administrative control. By contrast, private schools operate more autonomously, foster contact between staff and parents, and develop a common educational basis within the school. Furthermore, the quality of school boards makes a difference. This is also true when student background and school characteristics are taken into account. The cooperation between school board, school faculty, and parents (involved in school life) can have a particularly positive effect on student achievement.

All of these three aspects that affect the structure of educational systems are relevant in defining variations in the effectiveness of the two sectors. According to the analysis, differences in funding possibilities, administrative structures, and community involvement and choice, all affect student achievement. The latter is higher in private than in public education. Consequently, countries such as the Netherlands and Belgium, which have a large private education sector (>30–100%), score higher on quality and equity than Germany and Sweden, which have a smaller private sector involvement (<5%). France and Italy with their medium-sized private sector score in between the two (5–30%).

Countries with a relatively high percentage of students in grant-supported educational institutions perform better in terms of quality when compared to countries that are dominated by the public sector or countries where the proportion of students attending grant-supported institutions is small (<10%). Countries with a relatively high percentage of students attending grant-supported schools tend to perform better than others in terms of equality. The gap in the mathematics performance level between native students with a low socioeconomic status and native students with a high or medium socioeconomic status tends to be smaller in these cases. When we look at the issue of funding and financial basis, we see that education expenditure per capita or as percentage of gross domestic product is not directly related to educational outcomes.

Even though he leaves out Scandinavia in his analysis, Kerckhoff's (2001) attempts to compare the effect educational systems have on social inequalities in educational outcomes is a valuable piece of research to consider. He argues that a society's educational institutions can be described as the 'sorting machine' that stratifies its population. He then identifies four comparative characteristics: stratification, standardization, vocational specificity, and choice. Here, conservative states rank high on stratification and vocational specification while liberal states rank low. This may to a certain extent support existing policy traditions (**Table 2**).

In summary, all studies mentioned point to difficulties experienced in comparing educational systems. This is due to the large policy differences between these systems, and their resulting effect on education. All studies further demonstrate that the structure of educational systems depends on the individual countries' historical and political context.

The Influence of Welfare Policy on Educational Achievements

The characteristics of the prevalent educational policies in the particular types of welfare states are decisive for the results produced in the respective educational system. Nowadays,

Table 2 Characteristics of educational systems and their effect on social stratification processes

Dimensions	*High*	*Medium*	*Low*
Stratification	GER	UK	FR, USA
Degree to which systems have clearly differentiated types of schools whose curricula are defined as 'higher' and 'lower' (…) program offerings in secondary school are associated with different degrees of access to opportunities (for additional advanced schooling)			
Standardization	FR	GER, UK	USA
Refers to the degree to which the quality of education meets the same standards nationwide (…) higher in states that are controlled by the central government			
Vocational specification	GER	UK	FR, USA
Extent to which educational systems offer curricula that are designed to prepare students for particular vocations and award credentials that are vocationally specific			
Choice	FR, USA	UK	GER
Extent to which students have opportunities to make choices			

In accordance with Kerckhoff, A.C., 2001. Education and social stratification processes in comparative perspective. Sociology of Education, 3–18.

there is an international consensus concerning the criteria according to which the standard of the educational balance sheet should be assessed. The following two goals are regarded as benchmarks:

1. The educational level of the population should be as high as possible when compared to the level of qualification and competencies achieved.
2. When compared to the differences in the level of education achieved by the various population groups according to gender and social background, the degree of inequality in education should be as low as possible.

Prior findings indicate that there is an increased probability for an accurate picture if various data sources are used. In other words, the strongest assessment programs will rely on a mix of different measurement tools. Indirect measurement tools include data from surveys of school principals, students, and/or parents. Other statistics include financing information as well as indicators of the quality and equity of education outcomes. Education at a Glance (OECD, 2011), for example, uses several indicators such as completion, repetition, and dropout rates. These measurement tools cannot reflect what students have learned or what they are capable of doing as a result of their education. They can, however, provide information on school characteristics (public/private, autonomy, management), student background (socioeconomic status, gender, ethnicity, immigrant background), and parental influence.

Direct measurement provides us with more evidence regarding the increase in students' knowledge and abilities over a period of time. National and international standardized tests, e.g., Programme for International Student Assessment (PISA) and Trends in International Mathematics and Science Study, are one type of direct measurement tool. Such standardized tests are designed to assess general education skills or measure the knowledge of specific disciplines. Information derived from this assessment can be used for a variety of evaluative purposes, e.g., to examine quality or equality issues (e.g., socioeconomic differences) in learning outcomes.

Educational Achievements in Different Welfare Regimes

By summarizing all the results of the studies cited, we can arrive at the following conclusions. The three welfare regimes clearly put different emphases on social and educational policies. The Scandinavian countries pursue policies that ensure extensive social and educational benefits. They divide their political authority and financial resources between these two fields. Countries within the conservative regime clearly prioritize social security politics, where educational policy is clearly of lesser importance. The liberal countries focus on 'investive' educational policy, which they regard as a substitute for 'non-investive' social security policy.

The Educational Level of the General Population

Empirically comparable international studies (OECD, 2010) are first utilized to evaluate the success of the three chosen prototypical countries in their attainment of their goal of improving the educational level of the population, i.e., raising the qualification and competence level of the general population:

- Sweden uses a dual combination strategy of focusing on status security and investment in order to ensure that every member of the population attains the status of a top performer. According to the results, the well-balanced investment in (1) educational expenses designed to strengthen the developmental possibilities and the status-acquisition of young members of the population and (2) the social protection that ensures that the status of all citizens is stabilized has stood the test of time, even in crisis situations. This dual strategy that cultivates achievement potential and encourages qualified citizens to choose their own professional path has proven immensely successful.
- By comparison, the political tradition of the market-oriented and liberal United States has had little success. Even though the country has invested a higher percentage of the gross national product in their educational system than Germany, the educational results are not as good comparably. This leads to the conclusion that the educational outcomes in modern welfare states are particularly high if citizens are assured that their status will be secure after the completion of their education. This signalizes to the citizen that the state is concerned with their continued well-being. The United States is one of the countries that does not meet these conditions. Early investments in the educational system are not supported by later investments and can thus not realize their full fruition.
- The policy pursued in Germany leads to moderate results – the investments in status achievement-oriented educational resources are relatively low. A large part of the gross national product is spent on the protection of the status that has been achieved. Only very few resources are devoted to the development of competences and potentials. It could be argued that the generous social security benefits provided to citizens after the completion of their educational training leads to a counterproductive effect – the educational system does not ensure that all opportunities for an optimal status achievement are used.

Obviously, the great success of the Scandinavian regime in attaining the educational target 'quality' is the excellent strategy

of combining status-achievement and status-protection policies. According to Allmendinger and Leibfried (2003), the inherent logic of social security policies can be understood as a retrospective intervention since the adjustment of resources is not available to the unemployed. In contrast to this policy, which can almost be considered as 'rehabilitative,' this educational policy has an empowering 'habilitative' character.

What distinguishes educational policy from social policy is the prospect of intervention. Educational policy, an investment in the developing capacities, primarily of the younger members of the society, opens a chance for them to become an integrated member of the workforce and also provides the opportunity of further education in the course of their career, and thus the opportunity to maintain their professional competence. In this sense, social and educational policies should be understood as two complementary political intervention strategies. If the goal is a comprehensive welfare policy, they must not be played off against one another.

The Degree of Educational Equality According to Social Background

Prior evidence shows that a balanced combination of social and educational policies must go hand in hand with an effective organization of the educational system if the second goal of educational policy, i.e., as much equality as possible in educational quality among population groups from different backgrounds, is to be achieved. On the basis of previous findings, Schütz et al. (2008) have identified three criteria that best pinpoint the greatest effect that social background has on the performance record:

1. The highest possible number of children in the preschool sector.
2. The longest possible stay of the children in these institutions.
3. The differentiation and placement of children in different types of schools according to their achievement follows as late as possible.

Each of these characteristics raises the potential of the educational system to increase the academic achievement level of all children, irrespective of the input received in the parental home. It especially raises the academic performance of children of lower social origins.

Subsequently, the question is how the countries of the three welfare regimes 'perform' when these criteria are taken into account in cross-national studies (OECD, 2010).

- With only a few exceptions, the Nordic countries such as Sweden have the highest number of children in preschool institutions. They also have the longest possible time of stay. This can be attributed to the political philosophy that all citizens should be granted personal autonomy in shaping their lives as early as possible. The defined goal of this policy is to minimize the dependence on social background in children's performance development. Thus, equal social rights are attainable for all citizens. Hence, children are assigned to different types of schools very late.
- By comparison, in the Anglo-Saxon countries and especially in the United States, which is the prototype of a liberal, market-driven country, a considerably lower number of three- to five-year-olds is in public preschool institutions, where parents make a very low contribution or none at all. The ratio is approximately 60%, whereas the ratio in Sweden is nearly 90% (OECD, 2010). The amount of time the average child spends in preschool institutions is also shorter than in Sweden: 3 instead of 4 years. 'Tracking' only occurs late in the students' educational career.
- Similar to the United States, the conservative countries also have a low number of children in preschool institutions and also a shorter period of stay than in Sweden. In contrast to Sweden and the United States, a third factor, the very early 'tracking', i.e., the assignment of students to different school forms, is a defining characteristic for the regime in Germany. In Germany, children are normally assigned to different types of schools at the age of 10 years; in Sweden and the United States, this is only done at the age of 16 years. After that assignment to different types of schools or 'tracking', the developmental impulses offered by a heterogeneous student body are reduced. This negatively impacts the weakest performance groups: in Germany these are the students attending 'Hauptschulen' and 'Förderschulen' (Mutz, 2006; Demeuse et al., 2003). Consequently, student performance is more strongly influenced by social background. The path dependence of German educational policy is apparent here: from its traditional philosophy, German social welfare policy sees the family as the center of children's 'natural' social network. This has to be shielded as much as possible from any state intervention, even that of the educational system.

Table 3 provides us with a summary of the comprehensive typology of welfare regimes in developed countries, while taking their social and educational policies into account for further overview.

The results are thus fairly obvious: of all three educational systems, countries with a social democratic regime offer the best starting position. All other countries that wish to ensure a high level of education of their population can definitely be advised to incorporate these successful structural settings into their political tradition.

The Relevance of Education Policy in Developing Countries

Investment in education is crucial not just for the future welfare of highly developed countries. Also in the developing countries, the aims of education policy are twofold, encompassing both goals of efficient allocation and goals of equitable distribution. The results that have been reported from comparative research in highly developed countries are also valid for developing countries: the efficiency of a school system can be substantially increased by institutional reforms that focus on incentives for all actors in the system to increase the performance of students. Apparently, the combination of accountability (e.g., of teachers) and school autonomy (e.g., external tests with local decision making) is the most promising institutional structure. In addition, competition and choice between schools have a strong potential to shift school systems to a higher level of efficiency and equity.

Table 3 Comprehensive typology of welfare regimes in developed countries

	Welfare state regimes		
Characteristics	*'Social democratic'*	*'Conservative'*	*'Liberal'*
Freedom from servitude for all citizens (decommodification); financial assistance to secure means of subsistence	Extremely generous; universal for all citizens. Goal is the safeguarding of human rights and the freedom of all citizens from pressures of any kind	Generous; applies primarily to citizens in breadwinner roles. Goal is the safeguarding and strengthening of existing social networks	Severely restricted; only applicable to needy members of the population. Goal is the safeguarding of all citizens' productivity and their ability to support themselves
Relationship between the citizens and the state; social order (stratification)	To further social mobility through supporting all citizens, irrespective of background or gender in status attainment and status maintenance	To strengthen the established incorporation of citizens in social (family) networks and stabilize existing social stratification	To establish the self-reliance of all citizens; a targeted promotion of their status-attainment; encourage social mobility and personal responsibility
Relationship between social and educational policy	Combination of status attainment and status safeguarding for all age and population groups during the complete life cycle	Excessive focus on social (status-) safeguarding policy especially for population groups prior to entering a career and during their professional life	Intense advancement of education for age and population groups preparing for professional career; no comprehensive safeguarding of status for those who have been educated
Organization of the educational system	Multicentered with autonomous educational institutions, a unitary school system with few possibilities of choice	Centralized with dependent educational institutions; strongly differentiated school system with early division and selection into various school forms	Decentralized with autonomous but communally dependant educational institutions; late differentiation into various performance groups
Performance record	A high degree of social security; a high level of educational quality and low level of educational inequality	A high degree of social security; medium quality of education; high level of educational inequality	Low level of social security; low level of educational quality; medium level of educational inequality

Furthermore, it is very efficient to invest more money into preprimary education and to avoid early tracking of students into different kinds of schools. Greater competition and choice significantly raises both test scores and the productivity of schools. The effects of school choice are significantly larger for students attending subsidized private schools, and insignificant for students attending public schools facing softer budget constraints (Gallegos, 2004).

Colombia, Chile, and Mexico have been selected as prototypical examples for the connection between different (welfare) policy traditions and specific educational policy profiles in the educational systems that exist in Latin America as well as in other countries of the world (Gough and Wood, 2004). In all three countries, education outcomes are influenced not only by education policy, but also by public policy approaches in general. For education outcomes, an important factor besides education policy is family policy, because it has an impact not only on preschool education but also on health, nutrition, and emotional stability.

Most countries in Latin America have achieved universal primary education and are now witnessing a rapid expansion of secondary education. Latin American governments are committed to providing universal access to basic education, which includes primary and lower secondary education in order to assure a more successful transition from primary to secondary education. In Colombia, Chile, and Mexico, there are no significant gender differences when it comes to educational transition. The transition from primary to lower secondary education in 2005 in the prototypical examples selected was as follows: Chile (male 98% and female 98%), Colombia (90% and 90%), and Mexico (95% and 93%). These countries have experimented with a particularly wide range of governance reforms, such as increased school choice and competition through vouchers, conditional cash transfer programs to poor families, participation of parents and community in decision making, decentralization of government finance, and the use of information form learning assessments. However, these reforms have not unambiguously raised academic achievement standards. Often, they have widened inequalities (UNESCO, 2009, and UNESCO, 2008).

Citizens are encouraged to become wage earners demanded by the commodified labor market. The measures for commodifying the labor force include the enhancement of education and work training programs for qualified workforce. It is expected that education policy and public policy can improve the human capital and enhance the productivity of labor. Particularly, there is a linkage between learning outcomes and labor market needs. Nevertheless, according to PISA 2006, Latin American countries consistently perform at the bottom not only in the quality of outcomes but also in the equity of their distribution (learning opportunities). These low levels of cognitive skills can account for the low productivity, low wages, low social mobility, income and social inequalities, and poor growth performance of Latin America.

Applying the Welfare State Typology to Developing Countries

Not only in highly developed countries, but also in developing and threshold countries, has education become one of the most important drivers of a nation's economic growth because of its role in enhancing productivity. However, structural features of the traditional European and North American welfare states cannot directly be adapted to other parts of the world where states are faced with politically and socially challenging circumstances such as corruption, weak institutions, poverty, as well as imperfect and partial labor markets.

While the states in the advanced countries are trying to decommodify the labor force and reduce the social stratification and social inequalities by social policies, the states in developing countries are still pushing citizens toward being dependent on the labor market by qualifying and therefore commodifying their labor force. Thus, these countries are still far away from being real 'welfare states' by the standards of the highly developed world. In developing countries, a large proportion of the population is unable to deal with social risks by accessing state services or participating in labor markets. For this reason, individuals are required to rely heavily on family and communal arrangements. In general, gender (the importance of female spouses with paid work), unpaid work (the absence of robust labor and state institutions), and families (the presence of extended and compound families, the relevance of international remittances) are important to understand welfare mechanisms (Gough and Wood, 2004).

During the last decade, there have been several studies (e.g., Filgueira, 1998; Huber and Stephens, 2005; Rudra, 2007) that have tried to adapt Esping-Andersen's work to the Latin American context. Rudra (2007), for example, makes an important contribution by focusing on the question whether Latin American countries rely on public policies that predominantly promote access to the market (productivist regimes) or that predominantly protect people from the market (protectionist regimes). The author argues that Latin American countries and their 'welfare states' have a dual role of commodification and decommodification, where access to paid work cannot be taken for granted.

Gough and Wood (2004) point out that in Latin American countries, states in many areas of policy are practically nonexistent, labor markets often exclude the majority of the population, and a great deal of welfare production rests on families and social support networks. In informal welfare regimes, as found in Latin America, most of the population relies on family or community ties. Barrientos (2004) suggests that Latin America has shifted from a conservative-informal to a liberal-informal welfare regime. In the last two decades, collectively shared risks have become few, public policies have diminished, and individuals are increasingly on their own. Thus, the region resembles the liberal regime in developed countries; but unlike them, most countries in Latin American lack solid targeted state programs.

This is based on the valuable work done by Martinez and Vorrend (2009), after his consideration of Esping-Andersen (1990), Filgueira (1998), Gough and Wood (2004), and Rudra's (2007) studies on welfare regimes and welfare states, and based on his study of the complex interaction among the labor market, families, and public policy. Martinez and Vorrend (2009) goes on to identify the three welfare regimes in Latin American countries according to the following typology: protectionist, productivist, and familiarist.

Education Policy in the Productivist Welfare Regime

The productivist regime relies on the market and mainly on individually funded social security. Many individuals, particularly in middle-income sectors, fall between the cracks of targeted public policies and ineffective markets. A prototypical country of this regime is Chile. The country is trying to follow the liberal path and strengthen market forces for the development of the competences and the productivity of its population.

Education policy is part of this policy tradition. Chile tries to promote policy interventions to push forward equity and social mobility, in order to raise educational standards and improve the quality of education delivered. However, the accompanying legislative framework supports the perpetuation of a market-wise organized system that fosters competition and acts against a more equitable distribution of educational opportunity for all. There are inherent tensions here because of the complex relationship between the state and the market over the financing and delivery of education.

The transformative potential of education, its importance to national development and social cohesion, has been reflected in an increased share of public spending. Yet, while state investment has grown, so too has private expenditure as the cost of education is increasingly transferred on to individuals and their families by government financing initiatives. The tendency for children to attend schools with shared funding arrangements is higher among wealthier households, thereby increasing parental contributions to education. The shift from state schools to privately run establishments is continuing as these schools grow in number and their share of the total enrollment increases. The popular perception of private schools as providing a higher quality education than state schools is reflected in the changing distribution of student numbers.

Further, the socioeconomic stratification of the education system distributes access to quality education conditional on the purchasing power of the family. Yet, when the socioeconomic background of the students is factored in, the subsidized private schools perform no better than municipal schools. Consequently, private schools are failing to compensate for the social disadvantage of low-income children and to help in adding value for middle-class children. Therefore, further investment of state resources to subsidized private schools through a voucher system, and the further general expansion of this sector should be challenged as unlikely to provide a positive social return on public investment. The goal of promoting equity through a competitive, market-oriented, and socially stratified system must be questioned in terms of the state's capacity to influence and act in these areas, and the level of accountability to which schools in receipt of public funds are held (Matear, 2007).

Education Policy in the Protectionist Regime

The protectionist regime can be characterized as a state-stratified system whose targeting is based on collectively funding social security. In the case of Mexico, this policy has led to the creation of a fragmented, unequal, and incomplete welfare system that has excluded large sectors of the population, especially the rural workers and informal urban workers. Mexico is the typical example of a nominally universalistic model, modified in reality by fragmentation and embellished by targeted policies of low quality (Martinez and Vorrend, 2009).

In Mexico, there are wide disparities in quality between public and private schools. As a consequence, a higher proportion of middle-income groups has left public schools in search of better quality alternatives. The educational system is divided between those who can afford quality education and those who have to study in public schools.

For financing poverty programs that include an educational component, the Mexican government has increased state spending, often with direct credits from multilateral financial institutions like the World Bank. The most important antipoverty program Oportunidades, a conditional cash transfer program to the poor, provides resources to preferentially support the demand to cover the needs of a defined or targeted population. Oportunidades is a strictly targeted program mounted on universalist institutions like primary and secondary schools. It is a program of direct transfers, in cash and conditioned for selected poor households, and has a triple composition by which it seeks a sense of integration: support for education, health, and nutrition, with the goal of helping homes to overcome the intergenerational transmission of poverty. The educational component seeks to promote school attendance with educational support in grants for each of the sons and daughters studying between third grade of primary school and the third year of secondary school.

Education Policy in the Familiarist Regime

The familiarist welfare regime shows the poorest performance. Social protection and the formation of human capital are minimally decommodified. For education, commodification is the lowest in comparison to the productivist and protectionist countries, and wages are also the lowest. Colombia is an example for this regime. The vast majority of the population depends on familial and communal strategies in the context of exclusive labor markets (Martinez and Vorrend, 2009). This regime envisages a great number of dependent people who need to rely on the commodification of fewer available people.

Over the last two decades, Colombia has made great strides in improving access to education and has made some improvements in internal efficiency. However, it faces challenges such as low completion rates in secondary education, inequality in access and attainment, and poor quality of education. Primary education is mandatory through primary enrollment and is beginning to reach universality. Important gains have been made in secondary enrollment and completion rates; however, serious problems with enrollment and retention at upper secondary grades persist. Some possible reasons behind the high dropout rate at the secondary level include (1) concerns about the high cost of education (distance to schools, cost of tuition and supplies, etc.), (2) increasing opportunity costs for older students (making education less attractive than working), (3) low quality and relevance of learning, and (4) the lack of realistic opportunities to continue education beyond the secondary level. Disparities in enrollment and completion also exist between poor and rich regions and urban and rural areas. This disparity has been associated in part with the political and criminal violence that still prevails in some rural areas (**Table 4**).

Table 4 Typology of welfare state regimes in developing countries

Variables and indicators	*Cluster 1: Productivist Chile*	*Cluster 2: Protectionist Mexico*	*Cluster 3: Familiarist Columbia*
Commodification 1	High	High	Low
Effectiveness of labor markets to incorporate and remunerate the labor force	Highest	Medium	Lowest
Formalization of the labor market (occupied salaried workers)	Highest	Medium	Lowest
Income levels	Highest	Medium	Lowest
% Of population below poverty line	22.7%	28.86%	53%
Remittance (the importance of transnational commodification of the labor force)	0.10% Of GNP	1.05% Of GNP	More than 6% of GNP
Rural population	12%	23%	More than 30%
Decommodification 2	High	High	Very low
Proportion of the EAP occupied in the public sector	Highest	Somewhat lower	Half or less than half of what is found in clusters 1 and 2
Social expenditure in health and education	Highest	Mexico: Between clusters 2 and 3	Consistently much lower than in clusters 1 and 2
Fiscal priority (or effort) devoted to social policy as % of GNP	Less than in cluster 2	Mexico: Lower than in cluster 3 (9.8% in comparison with an average of 19% in cluster 2)	Lowest
Proportion of salaried workers with social insurance	Less than in cluster 2	Highest	Quite low
Private education enrollment 3	Highest (36%)	Lowest (13.46%)	Medium (between 26 and 28%)
Defamiliarization	High	High	High
Extended and compound families	Lowest	Lowest	Highest
Full-time female unpaid work	Central role	Central role	Central role
Nuclear families with spouses devoted to full-time unpaid work (the traditional 'male breadwinner' family model)	Higher	Higher	Lower than in clusters 2 and 3
Demographic transition	Advanced	Somewhat less	Incipient
Population of children under 12 years	25% Or less	25% Or less	30% Or more
Important role of families	Nuclear families (less burdened by dependent family members)	Nuclear families (less burdened by dependent family members)	Extended families (greater number of dependent people who need to rely on the commodification of fewer available people)

GNP, gross national product.

Consequences for the Future Development of Educational Policy

As our analysis has shown, there is an internationally comparable relationship between welfare traditions and educational policy. This is evident in both highly developed as well as in developing countries, and affects the educational results within each specific country and cluster. There are unambiguous correlations between

1. the educational success of a country as measured against the attained quality of educational rate of return and the equal distribution of these returns according to social background
2. and the importance accorded to educational policy in comparison to social policy and the resultant organization of the educational system in the respective country.

The comparison between countries characterized by these various welfare regimes serves to illustrate the relationship between welfare policy and the educational balance sheet, and their unequal distribution. These countries could be seen as 'real-life prototypes' of the three ideal types of welfare regimes, or alternatively, could at least be analytically approached from the perspective of such welfare regimes. At the same time for the case of Latin America, variations across regimes are significant: (1) the Productivist regime performs better in the supply of salaried work, (2) the three regimes have variations in social policy reforms, and (3) the three regimes have variation in allocation of social public expenditure. Our findings provide support that particular kinds of welfare regimes have distinctive educational policy profiles, and that particular kinds of welfare regimes and their educational policy have an influence on their educational outcomes.

Overall, each of the three welfare regimes provides diverse educational scenarios that alter the architecture of social policy. What clearly shines through the findings and research done is that the basic components of education and social policy of countries within the social democratic cluster should be a model and adopted by the countries that fall under the other

regime types. In Latin America, there is also much to be learnt by paying attention to which of the policies within the clusters produces the best results so that they can be adopted as well in other cases. But first, further research will be required in order to analyze how in the face of high path dependency other regimes could adopt certain components from countries with effective social policies, and in what way they could be implemented successfully.

These approaches demonstrate that a comprehensive typology of the welfare regimes should expand the seminal work achieved by Esping-Andersen and should include educational policy alongside social security policy. The research clearly confirmed how effective investment is in the preschool sector, not only in increasing performance, but also in combating inequalities. Our analysis has shown that not only social policy – as a policy that protects quality of life and the attained social status also in crisis situations – is influenced by the deeply rooted power structures and traditions characteristic for a specific welfare system, but also educational policy is significantly determined by the traditions adhered to by the welfare states. Educational policy as the policy that grants status attainment is likewise path dependent: it is impacted by the elementary commercial, legal, and institutional focus that gives social policy its direction.

Acknowledgment

The information about the Latin American countries was compiled by Nancy Cieza. We are very grateful for her assistance.

Abstract

All industrialized countries have welfare or social assistance programs intended to provide income support to low-income families. Such programs have the potential to reduce work effort among recipients and the research evidence indicates that such incentives exist and are sometimes large in magnitude. Work disincentives can be ameliorated with financial and nonfinancial incentives such as job search assistance, sanctions, and work requirements. Earnings subsidies are one way to provide financial incentives to those with very low-work capacities.

All advanced industrialized countries offer welfare programs. Often they go by other names, such as social assistance or by special titles (medical assistance, food assistance, and so on), but the common feature of all programs of this type is that they are 'means-tested.' A means-tested program is one that provides benefits or other support only to families or individuals with income or assets below some threshold. There may be other eligibility conditions in addition to low income or assets – such having a disability, having children, or minimum work requirements – and the threshold may vary across individuals and families of different types; but low income is always one of the conditions. Means-tested programs are often contrasted with universal programs, which provide some kind of government benefit to all those in the population, regardless of income, and are often further contrasted with social insurance programs – such unemployment insurance or retirement benefit programs, for example – where the primary condition for eligibility is that the individual has been employed at least to some minimal degree in the past. In social insurance programs, even high-income individuals can receive benefits if they satisfy this criterion. Having said this, however, while eligibility for social insurance programs is not based on low income, the level of benefits paid to recipients are sometimes income-conditioned (i.e., reduced or eliminated if current income rises above certain levels), which creates work issues similar to those arising for welfare programs.

Although the common element of all welfare programs is that they are means-tested, they vary tremendously in other dimensions both within countries and across countries. Some are broad-based, offering benefits to all or at least large swaths of the low-income population, while others are targeted on children, the disabled, the elderly, or other groups, which are judged to be particularly deserving. Some programs are offer 'in-kind' benefits, meaning that specific consumption items such as food, housing, or medical care are provided, as opposed to simple cash payments. Another important distinction is whether the programs are operated through a country's social welfare agency or through its tax agency. While most programs are operated through social welfare agencies, provisions in the tax code, which reduce tax rates or tax burdens specifically for families with low income, are functionally equivalent to a welfare program, and should be considered as such.

Programs in different countries also vary dramatically in their benefit levels and whether they impose behavioral requirements. Table 1 shows that the benefit level in social assistance programs in selected OECD countries ranges from 5% of the average wage in the U.S. to 31.5% in Denmark and Ireland for the head of household, with similar variation for spouses and children. Most countries have some sort of job search requirement and more than half have some kind of work requirement (these requirements will be discussed further below).

This article will discuss how welfare programs relate to work. Since welfare programs provide benefits to those with low income, it is necessarily the case that program recipients will have lower levels of employment and earnings than individuals in the general population. Ideally, governments should address the problem of low employment and earnings of welfare recipients directly by devising education, training, and other programs that increase their work and income levels and hence reduce or eliminate the need for individuals to receive benefits in the first place. However, this is very difficult to do, especially in the short run. Consequently, most programs aim

Table 1 Social assistance programs in selected OECD countries, 2010

	Benefit level as a percent of average wage			*Behavioral requirements*	
	Household	*Spouse*	*Per child*	*Job search*	*Work*
Austria	13.4	8.9	4.3	No	No
Belgium	20.1	6.7	3.5–8.5	No	No
Canada[a]	15.7	11.4	1.3–1.4	Yes	Yes
Denmark	31.5	31.5	10.0	Yes	No
France	15.8	7.9	4.7–6.3	Yes	No

instead simply to provide some kind of benefit or support to those with low-employment levels in order to raise their income and consumption to some minimal levels. When doing so, however, there is an incentive for individuals to reduce their work levels to make it more likely that they are eligible for the program or to increase the benefit payments they receive if already eligible. This trade-off between offering needed assistance to low-income families and discouraging them from working has been the central theme of much of the research on this topic.

The discussion below will first review the theory and evidence on this classic trade-off and how the use of financial incentives can ameliorate the trade-off. Following that, the discussion will turn to programs such as job search requirements, work requirements, and active labor market policy programs that attempt to ameliorate the trade-off through nonfinancial methods. A different type of financial incentive, through the use of earnings and wage subsidies, is discussed in the next section. The last section discusses dynamic incentives for human capital formation and related behaviors.

Work Disincentives: Theory and Evidence for Classic Open-Ended Programs

The eligibility and benefit determination for a 'classic' open-ended welfare program – that is, one that simply pays benefits according to the level of income and has no other restrictions or conditions on eligibility or benefit receipt – is illustrated in Figure 1. Letting the monthly benefit be noted by B, the formula for the benefit is $B = G - tE$, where G is the so-called guarantee level, E is the level of the family's earnings, and t is a taper rate (also called a tax rate or benefit–reduction rate). It is assumed that the family has no unearned income. The guarantee is the level of the benefit when a family has no earnings, and hence family income is guaranteed to be at least this high. The horizontal axis in Figure 1 shows the level of earnings (E) and the vertical axis shows the sum of E and B, or total income. When earnings are zero, total income is G. As earnings rise, B is reduced by t for every additional dollar of earnings along line AD. When earnings rises to E*, the benefit falls to zero and the family is no longer receiving benefits.

Figure 1 Classic open-ended welfare program.

This program increases family income but also creates work disincentives. Some individuals in families may reduce their earnings to zero in order to receive the maximum benefit, G; others may reduce their earnings in order to receive a higher benefit, B, since B is inversely related to earnings; and some individuals may initially have earnings above E* and hence be ineligible for any benefit at all but may reduce earnings to some level below E* to receive a benefit.

These work disincentives are affected by the level of G and t. A higher G will increase all the work disincentives just mentioned. A higher t will have ambiguous effects on total work disincentives, however. Line AD′ shows the benefit formula when $t = 1.0$, or what is called a 100% taper rate program. Intuitively, one would expect a higher taper rate to increase work disincentives because individuals who increase their earnings now have their benefits reduced dollar-for-dollar, and hence their total income is no higher than before. While this is correct, it is also true that some individuals – specifically, those who were working between E* and E*′ – are no longer eligible for the program and they will increase their work levels and earnings when they leave the program. Some of those with earnings below E*′ will also choose to go off the program and work and earn more, as well, instead of accepting a much lower income by staying on the program. The net work incentives of changing t are ambiguous in sign – they may reduce or increase work effort and earnings (Gruber, 2007; Moffitt, 2003). The work-discouraging effect is most heavily associated with the work of Milton Friedman (1962), who emphasized the first effect, but his analysis ignored the second effect.

There are many variations on this simple benefit schedule across programs and countries. Sometimes the program allows a 'disregard,' or 'exemption' level of earnings, so that benefits do not fall at all for some quantity of earnings. Sometimes a separate upper limit on earnings for eligibility is set below E*, which implies that benefits suddenly are eliminated if earnings go just above that, creating what is called a 'notch' in the benefit schedule. While all of these variations affect the magnitude of work disincentives as well as whom they affect (e.g., individuals with zero income versus those with higher income), the fact that benefits must be reduced, on average, as income rises and that they must fall to zero beyond some income level, means that some work disincentives will remain.

Even if the taper rate is set at a low level, in the hope that, on net, work disincentives will be reduced, the government has to be mindful of the fact that most countries have multiple welfare programs to serve different purposes. It is possible for a family to receive benefits from more than one, e.g., from cash welfare programs and housing subsidy programs. In this case, the total, or 'cumulative' taper rate is the sum of the taper rates of all programs the family receives benefits from (assuming the programs do not count the benefits of other programs as income, which makes the total taper rate not exactly the sum of the individual program taper rates). Even if the individual taper rates are low, therefore, the total taper rate can be high. If the family also has to pay positive taxes in the form of payroll taxes or income taxes, the total taper rate is even higher and possibly even above 100%.

The fact that open-ended welfare programs almost inevitably have some work disincentives does not mean they are not

socially desirable. Rather, they are an unfortunate side effect of accomplishing the socially desirable goal of providing financial support to needy persons and families. Since the goal of welfare programs is to provide assistance to those in need, the existence of work disincentives implies that some of those are not as needy as they appear, for they have reduced their incomes voluntarily because of the presence of the program. Nevertheless, this social cost may be outweighed by the social benefit of increasing incomes.

A relevant phenomenon that has been recognized in the research on welfare programs is that some families who are financially eligible for support (e.g., their incomes are below E*) do not participate and receive benefits. This is often described as a 'take-up rate' that is less than 100%. Why some families do not receive benefits even if they could has been the subject of much discussion. Moffitt (1983) supposed that it might be a function of 'stigma,' meaning a desire not to be a welfare recipient, even if it were to provide an increase in income. However, other research has revealed that nonparticipation can be a result of lack of information about eligibility, or because the time, money, and hassle costs of having to spend time with the welfare bureaucracy makes the benefit not worth applying for (Currie, 2006). The relative importance of different factors affecting the take-up rate are not fully understood.

Average effective tax rates facing low-wage individuals are very high in OECD countries (OECD, 2013). For example, a lone mother with two children in 2011 whose wage is one-third of the average wage in her country faced tax rates ranging from 5% in the U.S. to 127% in Denmark, with an average of 62% across all OECD countries. Tax rates for married couples and for those with different numbers of children were equally high and only slightly smaller for those with higher wages. This is important for the empirical evidence on the work disincentives of open-ended welfare programs indicates that those disincentives do exist. One of the more reliable pieces of evidence comes from a series of experiments in the U.S. which randomized families into groups, which either had no welfare program or offered a welfare program like that in **Figure 1**. The findings indicated that prime-age husbands reduced their work effort by 7% and wives reduced theirs by 17% (Burtless, 1987). Single mothers also reduced their work effort by 17%. Most of the reduction took place by extensions of spells of nonemployment; relatively little took place by reducing hours of work while still working, not surprising given that it is often difficult to adjust hours of work on most jobs or to adjust hours by changing jobs. The findings also showed that increases in benefit levels increased the work disincentives but that increases in the taper rate had very little net effect on work disincentives, with the positive and negative effects canceling each other out.

These findings are consistent in nature, although not always in magnitude, by nonexperimental studies of individual programs in different countries, which resemble that in **Figure 1**, although often having rules differing somewhat from the classic type. The U.S. evidence indicates that welfare programs reduce work effort by 10–50% (Moffitt, 2003: p. 2418). Many similar estimates have been generated in other OECD countries (e.g., Gurgand and Margolis, 2008).

Welfare Program Features to Reduce Work Disincentives

A number of features of welfare programs have been introduced to reduce the magnitude of work disincentives. These include work requirements, job search requirements, the threat of sanctions, and general forms of activity requirements.

In its purest form, a work requirement forces benefit recipients to work some minimum number of hours in order to receive benefits. For an individual with a particular job or wage rate, this implies that benefits cannot be received if the individual is not working at all or has earnings below some cutoff point. The program in **Figure 1** has to be altered by eliminating benefits at all levels of earnings below whatever minimum cutoff the government sets. The effect of work requirements on work disincentives is to unambiguously reduce those disincentives, for individuals who would have worked below the minimum amount will increase their level of work effort as a result. However, the increases can happen in one or two different ways: the individual can either increase his or her work effort to achieve the minimum level and therefore qualify for benefits, or the individual can choose not to do that and not to receive benefits at all. In the latter case, while some individuals who are not working will simply continue not to work, consequently resulting in no change in work effort, some will work more in order to make up for the lack of welfare benefits, thereby increasing work effort. The likelihood that an individual will choose not to receive benefits and to work less than the minimum is correlated with their job qualifications, skill, and wage rate: those with more job skills will more likely comply and receive benefits, while those with lower skills and wage rates will be less likely to comply.

The empirical evidence on work requirements is scanty because they have rarely been implemented in the rather severe form being discussed here. Perhaps the most well-known welfare reform which imposed significant work requirements on a welfare program is that which occurred in the U.S. in 1996. Studies of the evaluations of the effect of that reform show that work requirements increased employment rates by about 10% (Grogger and Karoly, 2005: p. 139). However, much of this effect was achieved by causing women to leave welfare and not receive benefits at all.

Job search requirements can be thought of as a milder form of work requirement. In this case, the benefit recipient is required to engage in job search but not to actually hold a job, if no suitable job can be found. Such a program requires a set of rules specifying how job search has to be conducted. Sometimes the requirement specifies that recipients have to register with the government unemployment agency and participate in looking at job vacancies at the agency on some periodic basis. The requirement may state that some minimum number of employers be contacted every week or month. In other countries and situations, a job search requirement may state that benefit recipients have to attend special sessions at which they are taught job-seeking skills, possibly in addition to contacting employers. Job search requirements can also be combined in sequence with work requirements, by requiring the recipient to search for a job for several weeks but by then also requiring that the individual actually finds a job at the end of that period or risk loss of benefits.

The empirical evidence on how the imposition of job search requirements per se is will affect work levels again rather scanty, despite the fact that it is more common than pure work requirements. Gueron and Pauley (1991) reviewed a number of U.S. job search requirement programs for welfare recipients and found them to have positive, but small, effects on work effort. Job search requirements have also been studied in Unemployment Benefit programs, which have somewhat different populations than do welfare programs (namely, not as disadvantaged and low skill). Nevertheless, all Unemployment Benefit programs require job search by the unemployed individual and there is some evidence that they shorten the length of time spent unemployed (Johnson and Klepinger, 1994).

Sanctions are defined by benefit reductions that are assessed on benefit recipients for not complying with work requirements or job search requirements (or activity requirements, to be discussed next). The sanctions can be partial or full – that is, benefits can be reduced but not eliminated for noncompliance, or the individual and family can be completely discharged from the program. In some cases, sanctions are increased, starting with some benefit reductions for initial noncompliance but then increasing in magnitude if noncompliance persists, possibly eventually resulting in complete benefit elimination Noncompliance means that the work requirements or job search requirements discussed above are not met, depending on the nature of the program. This can therefore mean not obtaining a job (in the case of work requirements), or not conducting a sufficient level of job search, or even not showing up for a special session to teach job search skills.

Theoretically, sanctions should clearly increase work effort relative to not having any sanctions at all. Evidence on this effect is difficult to obtain because all programs impose at least some sanctions, even if mild. The evidence that exists measures instead the effect of increasing or decreasing the level of sanctions. Studies in Western Europe show that sanctions in the unemployment insurance do speed up the transition from unemployment to work (Abbring et al., 2005).

Activity requirement is a broad term that is used to describe any type of requirement that states that the benefit recipient must spend a minimal length of time in some kind of activity. Work requirements and job search requirements and assistance therefore fall into this category, but the category also includes programs in which the individual is required to participate in an educational or training program. These latter programs have a rather different purpose, which is to increase the individual's level of human capital and future earnings. Training programs are, in fact, very common across industrialized countries, although they take many different forms, both informal and formal classroom training. Also included in the active labor market program category are subsidized public and private sector employment and, sometimes, sanction policies. These policies are common in Europe and evaluations of the various types indicate that subsidized public sector employment has little effect if not a detrimental one, while job search assistance and sanction policies have positive ones. Training programs typically have smaller positive effects and few positive effects on youth (Card et al., 2010; Kluve, 2010).

Earnings and Wage Subsidies

A more direct way to increase levels of work among welfare recipients is to actually reverse the problem induced by the taper rate by making the taper rate negative. A negative taper rate is an indirect way of saying that the benefit a recipient receives increases, not decreases, as the individual works more. However, since the program is still a welfare program, meaning that benefits are not provided to those with high income or earnings, benefits must eventually be reduced as income rises. But it is still possible to have a negative taper rate at lower levels of income.

If the benefit schedule is based directly on earnings, we have what is known as an earnings subsidy, as illustrated in **Figure 2**. If the subsidy is calculated as some fraction, s, of earnings, then every extra dollar of earnings raises total income by $(1 + s)$. In the diagram, the subsidy begins to be phased out when earnings reach E1*. The taper rate is labeled as t, which is the fraction by which the subsidy is reduced for each additional dollar of earnings beyond E1*. The subsidy reaches zero when earnings reach E2*.

A rather different program, called a wage subsidy, is one that subsidizes the hourly wage rate rather than earnings. If an individual is being paid $10 per hour, for example, and the wage subsidy is 10%, then the government would pay the individual $1 extra for every hour he works. The wage subsidy is phased out by decreasing the subsidy percent for those workers with higher wage rates, eventually eliminating it altogether at some wage rate picked as the eligibility point.

Most economists prefer a wage subsidy to an earnings subsidy because a wage subsidy does not ever have to be phased out for a given individual and hence there is no need to ever create the work disincentive that a phaseout induces. An individual with a low hourly wage continues to receive a higher benefit if hours of work increase, with no cap. Because an individual with a low hourly wage will never become a high-income person no matter how many hours he works, there is no danger of subsidizing high-income individuals. The work disincentive in a wage subsidy program comes instead from discouraging individuals from taking jobs with higher hourly wages or discouraging individuals from undertaking human capital investments by reducing the net amount by which the wage increases after such investments. This is a less direct work

Figure 2 Earnings subsidy program.

disincentive than that created by the earnings phaseout that must be present in all earnings subsidy programs. However, wage rate programs are rarely found for practical reasons. Government measurement of the hourly wage on a job is not easy, especially for workers who are not paid by the hour. In addition, in most forms of wage subsidy, the government has to track the individual's wage job by job, rather than by simply measuring total earnings over some time interval, and this can be difficult administratively if the individual changes jobs frequently, as many low-wage individuals do. Finally, there is an incentive for employers and workers to misrepresent hours of work by paying the individual by the week or month and then overstating the actual hours worked, thereby lowering the measured wage rate and increasing the government subsidy.

The more commonly observed earnings subsidies come in many forms. In the U.S., the main earnings subsidy works through the tax system and provides tax rebates according to family earnings up to a certain level of earnings, then holds benefits fixed over a second interval, then reduces them, eventually to zero, over a third and final earnings interval. In the U.K., the earnings subsidy has a minimum hours-worked requirement, but operates the subsidy through the employer who has to certify that hours are above the minimum. Above that minimum, the subsidy is eventually reduced. An earnings subsidy of this kind will not pay benefits to individuals who work part-time at low hours, unlike the U.S. program, which pays earnings no matter how low hours of work are. The UK minimum-hours program bears some resemblance, in fact, to a pure work-requirement program, which also pays no benefits to individuals who do not work at least some minimum number of hours.

However, this raises a separate important issue, which is whether the earnings subsidy program is a complete replacement, or substitute, for a traditional welfare program or whether it is just a supplement to such a traditional program. In the U.S., for example, no traditional cash welfare program is available at all many individuals – two-parent families, for example, or single childless men and women, no matter low their income. For those types of individuals, an earnings subsidy is not really a welfare program at all because it provides no support to those with zero or very low incomes, whose are the neediest individuals measured by income. But in the UK and in the US for individuals eligible for traditional cash welfare benefits (such as single-mother families), the earnings subsidy is layered on top of the traditional welfare program. In this case, since the traditional welfare program has a positive taper rate and benefits are reduced as earnings rise, the earnings subsidy merely counteracts that effect and reduces the taper rate (e.g., if the welfare program taper rate is 50% and the earnings subsidy rate is 10%, the net taper rate is now 40%). It is possible for the earnings subsidy rate to be so large make the net taper rate negative. In addition, when the earnings subsidy is layered on top of a traditional welfare program, the taper rate is actually increased at higher levels of income. That is because the earnings subsidy must eventually be phased out and, when that happens, the individual faces not only a taper rate on the traditional program benefit but also the phaseout of the earnings subsidy (e.g., if the traditional program taper rate is 50% and the earnings subsidy is phased out at 10%, the net taper rate is now 60%). Thus, work disincentives actually rise for individuals with earnings in higher ranges.

The empirical evidence on the effects of earnings subsidies on work indicates that they generally do have some positive effects on employment. In their summary of the literature on the U.S. program, for example, Hotz and Scholz (2003) find positive effects on the employment rates of single mothers but no effects on that of prime-age males and perhaps a small negative effect on the hours worked of married women. Findings in the UK are very similar, with positive effects on employment for lone mothers (Francesconi and Van der Klaauw, 2007) but small or negligible effects on married men and women as a whole, although married women married to men working low hours experienced positive effects (Francesconi et al., 2009).

Dynamic and Human Capital Effects

Dynamic work effects of welfare programs occur when the individual is forward-looking enough to anticipate work levels in future periods of life (future months, years, etc.) and alters his or her current work effort because of this. One simple effect that can occur is if the individual realizes that he or she can alternate periods of not working and being on the program with periods of working and being off the program in order to achieve a higher level of benefits than he or she could if he or she worked constantly halfway in between. In **Figure 1**, an individual who worked half the time above point E^* and did not work at all half the time would receive average benefits, which are above the schedule if the individual worked all the time halfway in between. This provides an incentive for individuals to cycle on and off the program. Another effect can occur if the individual is able and willing to save any of his or her welfare benefit for future periods when he or she is off welfare (this may be constrained by asset tests in the welfare program, which eliminate eligibility if the recipient has too much money in the bank). In this case, the individual may wish to reduce current consumption by not spending all of the welfare benefit and increase future consumption by saving some of it for later periods when he or she is off welfare. This extra income in later periods may reduce work levels even in those periods. A third dynamic effect can occur if an individual knows that his or her wage rate, or job opportunities more generally, are going to be different in the future than they are currently. If so, the individual may work more in the periods when job opportunities are high, and stay off welfare in those periods, and work less in those periods when job opportunities are low and stay on welfare (in the literature, this is known as 'intertemporal substitution'). This would therefore increase welfare program participation and lower work levels when on welfare. Some effect of this kind might also occur if a welfare recipient's job skills and wage rate increase, on average, over the lifetime (whether this happens for very low-skilled, less-educated individuals is an open question). If so, the individual may intentionally lower levels of work while young and receive welfare benefits, planning to go off welfare and work later when job opportunities are better.

A different set of effects occurs if the welfare program has time limits (the U.S. is the leading example of such programs,

although Unemployment Benefit programs in all industrialized countries are somewhat similar). If the individual is not forward-looking, then he will simply remain on the welfare program until benefits run out and benefits will then fall to zero. However, if he or she anticipates the approach of the time limit, the individual may go off the program and work in order to 'save' the remaining periods of eligibility for periods later in life when job opportunities are particularly bad or when the individual is laid off from his or her job. By 'saving for a rainy day,' work effort is increased in current periods when the individual goes off the program and decreased later when he or she returns to the program.

Human capital effects occur if the individuals consider making investments in their skills either by attending school, undertaking training programs, or simply working in the hopes of raising future wage rates and job opportunities by acquiring work experience and seniority. Welfare programs have two different effects on the incentives to invest in human capital activities that take time (education, training). On the one hand, if the individual anticipates remaining on welfare even after the investment is complete, the 'return' to the investment is lowered because any higher future earnings result in lower future benefits, the amount depending on the taper rate, t. On the other hand, the opportunity cost of taking time off from work in order to attend school or a training program is also reduced by the welfare program – the amount of lost earnings is smaller because benefits would be reduced if the individual were to work instead of devoting time to human capital investment. The net effect on human capital investment is therefore ambiguous in sign.

A less ambiguous effect of welfare programs on human capital investment occurs if the individual is credit-constrained and cannot borrow for the direct costs of education or training or does not have alternative sources of income to support consumption while attending school or training. In this case, the welfare benefit provides, in effect, credit relief and allows the individual to undertake the investment and still have enough money to have at least minimal levels of consumption.

The effects on human capital investment that occur simply by working and obtaining more work experience and seniority (so-called 'learning by doing') are somewhat different, since that type of investment does not require time off from work, as education and training do. The positive taper rate in this case unambiguously reduces the return to work and hence reduces the incentive to work in order to increase future human capital as well. An earnings subsidy does the opposite.

The empirical evidence on dynamic effects is minimal. Keane and Wolpin (2010) estimate a life cycle model with welfare participation but focus more on the effects on the marriage market and racial differences. Sanders and Miller and Sanders (1997) investigate the effect of welfare on human capital accumulation, finding that many individuals do not go onto welfare because it will reduce their future human capital accumulation. There have been a small number of studies of the effect of time limits on labor supply as well, with mixed findings.

Welfare Economics

Yew-Kwang Ng, Nanyang Technological University, Singapore

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In this article, the conditions for Pareto optimality are outlined; why the first theorem in welfare economics is true is explained. Despite the required conditions being unrealistic, the first theorem is very important as it shows the working of the market mechanism and serves as a benchmark, allowing us to examine divergences caused by, say, external costs. Coase's argument against the Pigovian taxation of external costs, and of pollution, is based on all-or-nothing comparison ignoring an important asymmetry. Arrow's impossibility theorem and a 90% solution to the paradox of interpersonal cardinal utility are discussed.

What Is Welfare Economics? Preference versus Welfare

Welfare economics is the branch of study that formulates propositions by which we can say that the social welfare in one economic situation is higher or lower than in another. What is social welfare? It is the welfare of individuals in the relevant society. What is individual welfare? The welfare or well-being of an individual may be regarded as her net happiness. Although we typically use the term happiness for immediate feelings and welfare for longer-term well-being, these two are essentially the same for any given time period.

There is a distinction between welfare and utility or preference (*see* Welfare: Philosophical Aspects): in older times, economists used the term utility more in the sense of subjective satisfaction, closer to welfare. However, modern economists use utility just as a representation of preference. In this sense, the utility or preference of an individual may clearly differ from her welfare or happiness due to the following three factors:

1. An individual may ex-ante prefer or choose A over B but her ex-post welfare may turn out to be lower in A than in B due to ignorance or imperfect foresight. Harsanyi (1997) distinguished between actual preference and informed preference.
2. Although probably not accepted by the majority of economists, an individual may have non-affective altruism (Ng, 1999) and prefers A over B due to her concern for the welfare of others over and above any warm-glow effects (which is called affective altruism) that also improves her own welfare (*see* Charity and Philanthropy, Economics of).
3. Ignoring nonhuman welfare and regarding any divergence between preference and welfare other than ignorance and non-affective altruism as irrational, these three factors present an exhaustive distinction between preference and welfare.

Traditional welfare economics mainly discusses preference or utility; although much study has been done on happiness (Diener et al. 2010), attempts to deal with welfare/happiness have not advanced very far (e.g., Kahneman et al., 1997; Ng, 2003).

First and Second Theorems in Welfare Economics

The first theorem in welfare economics, a if not the most important result, states that under certain conditions, a general equilibrium of a market economy under perfect competition results in a most efficient allocation both in resource, inputs, or factors of production, and in final goods (taken to include services). Efficiency here is defined in the sense of Pareto optimality where no one can be made better off without making any other worse off. Perfect competition requires that all sellers and buyers have no influence on prices and take market prices as given. Apart from this (and the implied absence, at equilibrium, of increasing returns; see Ng, 2009), the main additional conditions are perfect relevant information and the absence of real external effects. A consumer needs to know that she can buy the various goods at the given market prices, and her preference for them; a producer of a certain good needs to know the best available method (i.e., the least costly method at the market prices of the inputs) of production. In contrast to real external effects like pollution as discussed in Section Some Welfare Economic Issues of Environmental Protection, the presence of pecuniary external effects does not cause any inefficiency, at least not under the classical conditions of perfect competition (and absence of distortions). Pecuniary external effects are those where the actions of someone affect others through the effect on the market prices. For example, the higher demand for good x by consumer A may increase its price and hence make consumer B (who also likes to consume good X) worse off. This does not cause inefficiency under perfect competition as the loss in consumer surplus by B is offset by the gain in producer surplus for the supplier of x. If conditions for the first theorem are satisfied, the situation is Pareto optimal both before and after the change in preference by A.

The condition of perfect relevant information may be significantly violated for certain goods where many consumers are ignorant of the quality of goods. This explains the need for certain government regulations, on food safety in particular. This is partly because the undesirable effects may not be clear and immediate, and are difficult to be attributed to particular goods. The presence of external effects like pollution is even more important and is discussed in Section Some Welfare Economic Issues of Environmental Protection.

The assumptions of perfect competition, no ignorance, and no pollution are very unrealistic; why else is the first welfare theorem important? This theorem may be misleading if not interpreted carefully. In fact, at least to some extent, the theorem probably has been interpreted incorrectly to support virtually 100% free-marketism (the case against the Pigovian

tax on pollution discussed in Section Some Welfare Economic Issues of Environmental Protection is probably related to this misinterpretation). However, if interpreted properly, the first welfare theorem is one of the most important results in economics. On the one hand, it allows us to focus on the essence of the price mechanism or market coordination in achieving efficiency in resource allocation, production, and distribution of products. On the other hand, it serves as a benchmark to identify the possible sources of inefficiency (e.g., monopoly, pollution, and consumer ignorance) and hence device possible corrective measures (e.g., eliminating administrative monopoly, taxing pollution, and appropriate food safety regulations) to supplement the market.

Why Is the First Theorem True?

To appreciate the essential functioning of the market mechanism, let us consider why the first theorem is true under its assumptions. Before this, consider first the necessary conditions for Pareto optimality. Given the amount of resources and amount of labor, we want to allocate these factors for production of various goods and services in an efficient way, to reach the production possibility frontier so that more output of one good is not possible without reducing that of another. This requires that the marginal rate of technical substitution (MRTS) between any two inputs (factors of production) used in the production of any good X must be the same as the MRTS between the *same* pair of inputs used in any other good, for example good Y. If the MRTS between any given pair of inputs (say, inputs A and B) are different in the production of X and Y, we can reallocate A and B so as to increase the output of either X or Y, or both. Suppose one unit of A can substitute for 3 units of B in the production of X but one unit of A can substitute for only 2 units of B in the production of Y. This suggests that A is relatively (in comparison to B) more productive in X than in Y. If we transfer one unit of A from the production of Y to that of X, the extra unit of A can release 3 units of B from X (while holding output unchanged), but we only need to use 2 units of B for Y to offset the loss of one unit of A there. Thus, we maintain the output levels of both X and Y unchanged, but with one unit of B left unused. Using it in the production of either X or Y, or both may thus increase the output.

The simple point made above may be shown graphically by inverting the isoquant map (not shown; with the amounts of A and B used in Y on the two axes) of Y by 180°, locating the origin diagonally north-east of the origin of the isoquant map of X; the width and height of this Edgeworth box represent the amounts of A and B available, respectively. The tangency points of the two sets of isoquants trace out the locus of productively efficient allocation of the two inputs between X and Y. Along this locus, the slope of the isoquant for X (MRTS between A and B in X) is equal to that in Y. This condition for productive efficiency is $MRTS^X_{AB} = MRTS^Y_{AB}$ for all inputs A and B used in the production of any goods X and Y.

Once goods are produced, we need to distribute them to various consumers efficiently. This condition for efficiency in exchange requires that the marginal rate of subjective substitution (MRS) between any two goods be the same for all consumers consuming this pair of goods, that is, $MRS^J_{XY} = MRS^K_{XY}$ for any two consumers J and K. The reason for this condition is similar to that for productive efficiency. If one unit of X can substitute for 3 units of Y for consumer J while it can substitute for only 2 units of Y for consumer K, transferring X from K to J, compensated by transferring Y from J to K could make both consumers better off.

If we satisfy both conditions (one for productive efficiency and the other for exchange/distributive efficiency), then will it be sufficient to ensure Pareto optimality? No, even if we ignore or assume the satisfaction of the second-order conditions (i.e., ensure a maximum rather than a minimum point), productive efficiency ensures no misallocation of inputs in production; exchange efficiency ensures no misallocation/distribution of the given produced goods to consumers. This is not sufficient for Pareto optimality because the given amounts of goods produced may not be consistent with the preferences of consumers. For simplicity, consider only two goods, food and clothing. We may efficiently produce an excessive amount of clothing and too little or no food; we have a lot to wear but go hungry. In contrast, we may have a lot to eat but go naked! This is far from efficient. To ensure that the amounts of the various goods produced are consistent with the preferences of consumers, we need the top-level optimality condition requiring the equality of the MRS between any pair of goods to be equal to the marginal rate of transformation (MRT, the rate at which one unit of a good may be transformed into another by reallocating inputs in the production): $MRS_{XY} = MRT_{XY}$.

Now consider how the invisible hand of the market mechanism achieves Pareto optimality. This depends on the assumed profit-maximization behavior of producers/firms and the utility-maximization behavior of consumers/individuals. Under the assumptions of perfect competition, no (relevant) ignorance, and no external effects, the maximization actions satisfy all the above three conditions for the Pareto efficiency (assuming the satisfaction of the second-order conditions like convexity of preferences or indifference curves curving the right way, and so on), as explained below.

Under perfect competition, all economic actors (consumers, producers, and input suppliers) have, each acting on her own, no appreciable influence on prices. Ignoring collusion (the presence of which violates the requirement of perfect competition), each takes prices as given (beyond one's control) and maximizes accordingly. Any consumer thus views her budget line as linear and maximizes utility by consuming at the point where the given linear budget line is tangent to her highest indifference curve (ignoring the goods she does not consume). As the slope of the indifference curve is her MRS between the relevant pair of goods and the slope of the budget equals to the price ratio of this pair of goods, we have, at the utility-maximization equilibrium point, $MRS_{XY} = P_X/P_Y$. As the same set of prices is faced by all consumers, and as all consumers who consume this pair of goods satisfy this same equation, the MRS of all consumers of x and y are equal to the same P_X/P_Y, and hence are also all equalized, satisfying the exchange condition as mentioned above.

Taking input prices as given, any producer of any good views its isocost curves/lines as linear (just like the budget line of a consumer). To maximize profit (which equals total revenue minus total cost), he must minimize the total cost of producing any given amount of output (which yields a given

amount of total revenue). Thus, for any output chosen, he chooses an input combination at a point where an isocost line is tangent to that isoquant. This means that the MRTS between this pair of inputs (given by the slope of the isoquant) is equal to the ratio of input prices (the slope of the isocost line). Because all producers of any good are faced with the same set of input prices, we thus have the MRTS between any pair of inputs used in the production of any good being equalized to their input price ratio, and hence equal to each other, satisfying the condition for the productive efficiency.

To maximize profit, a firm produces until its marginal cost (MC) curve just intersects its marginal revenue (MR) curve from below. The MR of a perfectly competitive firm is its horizontal price line or the demand curve for its product. Profit maximization thus entails price = MC. As this is true for all goods, we have $MC_X/MC_Y = P_X/P_Y$ for any pair of goods X and Y. In the absence of external effects, $MC_X/MC_Y = MRT_{XY}$. This is so because if we decrease the production of X by one marginal unit (tiny; the equality here is only approximately true for a large unit), we save inputs costing an amount of MC_X. If we use this amount of inputs saved for additional production of Y, then we can increase the output of Y by an amount that equals MC_X/MC_Y, making this the MRT_{XY}. From the above-mentioned two equations, we thus have $MRT_{XY} = P_X/P_Y$. As the exchange condition above already gives us $MRS_{XY} = P_X/P_Y$, we have $MRS_{XY} = MRT_{XY}$, which is the satisfaction of the top-level condition for the Pareto optimality.

Thus, we see that all the three conditions for the Pareto optimality are satisfied under the conditions stated. In addition to the absence of price-influencing effects and external effects, the exchange condition is satisfied by the utility maximization actions of consumers, and the production condition is satisfied by the cost minimization actions of producers. The top-level condition is satisfied by the interaction of utility maximization of consumers and profit maximization (including cost minimization for given output) of producers, coordinated through the price mechanism. In understanding how the three conditions for Pareto optimality are satisfied, we also understand how the market coordinates resource allocation to produce various goods to satisfy the preferences of consumers efficiently.

Second- and Third-Best Theories

Pareto optimality requires the satisfaction of all the three conditions in the production of all goods. If some of the conditions cannot be satisfied for some goods, is it better to satisfy as many others as possible? The theory of second best (Lipsey and Lancaster, 1956) says that it is, in general, not true. Given the violation of conditions for some goods as additional constraints, in general it is best to deviate from the conditions for all goods (except by coincidence)! This makes piecemeal welfare policies virtually impossible.

Suppose factory A produces good A with huge pollution. The first-best solution is to tax this pollution (see Section Some Welfare Economic Issues of Environmental Protection) according to the marginal damage of pollution. Suppose this factory is owned by a politically powerful person and no one dare tax A. Given this as a constraint, it might be better to deviate from the first-best conditions in all goods, for we may want to encourage goods that are very substitutary (in consumption and/or production) to A and to discourage goods that are very complementary to A to indirectly affect A to partially reduce pollution. This is the intuition of the second-best policies. However, the second-best policies require taking account of all the complicated interrelationships in consumption and production between all goods and inputs; these are informationally impossible and administratively very costly. Taking account of informational and administrative costs, second-best policies are neither feasible nor optimal. In the real world where second-best violations exist and informational and administrative costs are important, it is best to pursue third-best policies. Ng (1977, 2004a) shows that in the absence of sufficient information (Informational Poverty), the third-best policies are simply the same as first-best policies, like price = MC, or MRS = MRT. In the presence of sufficient information (i.e., informational scarcity), the third-best policies falls between the first-best and second-best policies, and account for more important interrelationships only. An example of such a third-best policy is subsidizing train travel (with less congestion and pollution per passenger) to reduce excessive car congestion and pollution, if the direct taxation of the latter is politically or technologically not feasible.

The Second Theorem

The first theorem refers only to efficiency, and it does not say anything about equality. A Pareto-optimal point (i.e., allocation of resources and goods) may involve the existence of extreme richness with extreme poverty. Could an efficient point with higher equality be possible? The second theorem says that any feasible Pareto-optimal point could be sustained as a perfectly competitive general equilibrium with the appropriate initial distribution of endowments (of resources, assets, and earning abilities, possibly including power and connections in a wider analysis). If we want an outcome of more equality, we need a more equal distribution of endowments. On the one hand, a Jackson ends up with a huge income/wealth level because he is endowed with a sexy voice and other talents, allowing him, with some learning/training, to attract thousands/millions of fans willing to pay highly to watch his performance. On the other hand, a Kwang ends up with only a small fraction of that wealth because when he sings, people run away!

If we start with very unequal endowments, could we improve upon the unequal outcomes to achieve higher equality? Yes, but under the traditional analysis, we typically have to sacrifice some efficiency. We may tax the rich more and help the poor. This does not only involve administrative, compliance (on the part of the taxpayers), and policing costs, but also disincentive effects, as it may make both the rich and the poor having less incentives to earn higher incomes. We may also add the costs of generating more rent-seeking activities, not to mention outright corruption. Thus, the second theorem has limited significance, but it does show us that the unequal outcome may largely be traceable to unequal endowments rather than the functioning of the market as such. Some recent studies have shown that some improvements in equality may actually be beneficial to efficiency. With the increase in within-country inequality over

the past few decades, there have been significant increases in public support for more redistribution (IMF, 2014).

The question of efficiency–equality tradeoff alerts us to the limit of Pareto optimality. Most changes make some people better off and some worse off. Therefore, we have to go beyond Pareto optimality, as discussed next.

Social Choice (*See* Public Choice Economics)

How does or should a society decide especially in the presence of conflict of interest? Arrow (1951/1963) asks whether we can have a reasonable rule that allows us to derive our social ranking/ordering of relevant alternatives/social-states from the individual orderings of them. The answer is 'no!' even if only a few very compelling conditions are required: individual freedom to rank, weak Pareto (if all individuals prefer x over y, the society must also so prefer), independence of irrelevant alternatives (ranking of x vs y not depending on z), and non-dictatorship (nonexistence of a single individual who dictates all choices).

This Arrow's impossibility theorem, although appearing to be surprising to many and generating a large amount of debate, may actually be explained quite simply. Since the social ordering has to be derived only from individual orderings (of social alternatives), it effectively ignores the intensities of preferences. A preference situation of:

x, y,……, z (Situation 1)

and another of:

x, ……, y, z (Situation 2)

are taken as exactly the same: the ordering being x above y which is in turn above z. The possible huge difference between the two situations with the intensity of preference of y over z being much higher than that of x over y under situation 1 and the reverse under situation 2 is completely ignored.

True, it is more difficult to obtain information regarding the intensity of preference than regarding just the ordering, especially if the intensities have to be interpersonally compared. Thus, Arrow's problem is not unimportant. If we could make do with easier obtained information, our life would be easier. But the answer is, again, 'no!'; we cannot just rely on individual orderings. The intuition of this impossibility is also clear. If one has a number of children and has to make collective decisions for the whole family, he obviously would not only want to know the ordinal ranking of the alternative options by his children, but also to know how strong their preferences are. Thus, Arrow's impossibility suggests that reasonable social choice should not only be based on individual orderings, but should also take into account the intensities of preferences or cardinal utilities. Moreover, since more than one person are involved, interpersonal comparisons of individual cardinal utilities are also necessary (Sen, 1970).

How do we solve this paradox/dilemma of interpersonal cardinal utilities (that interpersonally comparable cardinal utilities are needed, but they are difficult to obtain)? One option is to improve on the obtaining of the required information, including perhaps the further development of happiness studies (e.g., Diener et al., 2010; Ng, 2013). Before substantial advances on that front, perhaps we may solve the dilemma largely (90%?) by using the willingness-to-pay (information on which is relatively easier to obtain) as the measure of the intensity of preferences. However, this raises the interpersonal or equality issue. The willingness of a rich person to pay $10 000 may be much larger than that of a person of average income to pay $1000, but need not be so in terms of welfare or happiness. This problem is solved by treating a dollar as a dollar but using redistribution to address the equality issue, as it is more efficient to achieve any desired level of equality in real income (utility/welfare) by adopting a purely efficiency-oriented policy in specific issues, and do redistribution in the general tax-transfer system (Ng, 1984). This proposed solution is only about 90% workable since we still need interpersonal comparison of cardinal utilities in determining the optimal tradeoff between efficiency and equality in the general tax-transfer system. But this, at least, frees us from the informationally demanding need in all specific issues (*see* Cost–Benefit Analysis).

Attempts to bypass Arrow's theorem do not seem to be convincing. For example, Little (1952) and Samuelson (1967) argue that the theorem is only relevant to politics, not to welfare economics as the latter does not have to deal with changes in individual preferences. Kemp and Ng (1976) and Parks (1976) show that, even holding individual preferences unchanged, if we insist on using ordinal information only, impossibility results still hold, as generalized by Roberts (1980).

Even if we have interpersonally comparable cardinal utilities, we still have the problem of as to which specific a social welfare function (SWF) should be maximized. In particular, should the society maximize the classical utilitarian SWF of the unweighted (or equally-weighted) sum of individual utilities? Harsanyi (1953, 1955) and Ng (1975) provide compelling arguments for utilitarianism. Harsanyi uses the reasonable conceptual method of impersonal reasoning and reaches utilitarianism compellingly. This is more widely known as the 'veil of ignorance,' a term invented by Rawls (1971) who gave Harsanyi only an obscure footnote. Although he uses the same impersonal reasoning (Hare's rule of universalizability is on a similar principle; see Sen, 1966), Rawls reaches rather inextricably the virtually opposite SWF of maximizing the utility level of the worst-off person. Some people believe that this is based on the principle of extreme risk aversion. There are two important problems with this. First, although one may rationally be risk-averse with respect to some objective/instrumental variables like consumption/income levels due to diminishing marginal utility of consumption/income/wealth, she should not be risk-averse with respect to the ultimate objective like utility/welfare/happiness. Logically, one cannot have diminishing marginal utility of utility! Secondly, even if it were rational to have risk-aversion with respect to the ultimate objective, an extreme degree of risk-aversion is certainly not acceptable. Being willing to sacrifice enormously the welfare of all others including the second worst-off person for a marginal increase in the welfare of the worst-off cannot be rational. Its apparent attractiveness to many philosophers and economists may be explained by the confusion of nonultimate considerations with basic values (Ng, 1990). The extreme emphasis on those at the bottom

cannot be justified on their marginal increases in welfare alone, and must be explained by the indirect effects in the future through improving equality, harmony, etc. This should be achievable by a (even if purely utilitarian) SWF that takes into account effects on all, and also of the future.

Harsanyi asks us to imagine: Suppose you were an unincarnated soul, having 1% chance of becoming (both in objective circumstances and in subjective capabilities, including preferences and the capacity for enjoyment) each of the 100 individuals of a given society. You have to decide before incarnation what SWF would you like the society to maximize in making social choices? If you are rational, you should choose to maximize your expected utility/welfare by requiring the future society to maximize the utilitarian SWF of the equally-weighted sum of individual welfares. This maximizes your expected utility while you are still under the veil of ignorance. People with good moral intuition should find this reasoning compelling. Ng (1975) also argues that our SWF should be utilitarian, based mainly on finite sensibility with weak majority preference: If at least half of the individuals prefer x to y and no one prefers y to x, social welfare is higher in x (see also Economics and Ethics; and Mueller, 2003: Chapter 23).

Occasional pronouncements or lamentations of the death of welfare economics is based on the impossibility of interpersonal comparison of utility/welfare. Salles (2014: p. 8) is correct that "welfare economics is alive and well in multiple guises." Also, Atkinson (2011: p. 157) argues that "welfare economics should be restored to a prominent place on the agenda of economists and should occupy a central role in the teaching of economics."

Many issues related to social choice have been explored. For example, individuals may misrepresent their preferences; could we design voting/aggregation rules that are strategy-proofed? Difficulties abound see pioneering studies by Gibbard (1973), Pattanaik (1973), and Satterthwaite (1975) and a survey by Barberà (2011); on issues of distributive justice, see, for example, Fleurbaey (2008), Gotoh and Dumouchel (2009), Kaplow and Shavell (2002), Kolm (1997, 2005), Moulin (2003), Ng (2000), Roemer (1996), and Sen (2009); also articles Equality; Income Distribution and Inequality: Measurement Issues; on individual freedom and rights, see, Pattanaik and Xu (1990), Dowding and Van Hees (2009), Sen (2002), and Suzumura (2011). Although there are also many important issues that are closely related to welfare economics, only the most important issues are discussed in the following section.

Some Welfare Economic Issues of Environmental Protection (*See* Environmental Economics)

With the threat of global warming, environmental protection and sustainable development have become very important issues. It is widely believed that this is essentially the issue of intertemporal ethics. If we produce, pollute, use up resources, and consume more now, we leave less to the future generations. In fact, why sustainability may be threatened is not mainly due to the disregard of the present generations for the welfare of future generations, but the failure to avoid excessive environmental disruption now. This is essentially a question of I/we versus others; one of external costs, not of intertemporal ethics. In fact, the free market takes care of the intertemporal allocation rather efficiently partly due to the largely sufficient (if not excessive) care of most parents for their own children due to both biological instinct and education/learning. In addition, under sufficient property protection, an old man does not have to hastily exhaust the minerals under his land; he could sell it to younger men who have longer time to use the land more efficiently. In the absence of ignorance and other imperfections, resource utilization will be intertemporally efficient (Hotelling, 1931), as consistent with the first theorem discussed earlier.

In the presence of important external effects like greenhouse gases and other pollution, the first theorem no longer holds, and governmental intervention in the form of Pigovian taxes on external costs in accordance with their marginal damages may improve efficiency. However, Coase (1960), Cheung (2013), and others argue against the Pigovian taxation of external costs, or even the concept of externality as such. This position has been debated. It may be conceded that Coase's point on the two-sided nature of the problem is correct. Restricting pollution benefits the sufferers but affects the polluters. Secondly, if the two parties may negotiate without prohibitive costs to reach an efficient solution, no government intervention is necessary. The externality is 'internalized' through negotiation. We may even concede the so-called Coase's theorem that such an efficient outcome will be reached whether we start with polluter's rights or with amenity rights; in the absence of transaction costs (including game-strategic behavior preventing agreement), an efficient outcome will be reached. However, Coase's case against the Pigovian taxation of external costs, even in the presence of transaction costs preventing mutual agreement, has been argued (Ng, 2007, 2014 on which the following is based; really just textbook with a crucial epsilon) to be based on an unacceptable all-or-nothing comparison only.

The problem may be shown by using the textbook analysis of an external cost in **Figure 1**. The horizontal axis x measures the amount of some activity/pollution/emission that yields a (net) marginal value (MV) to the polluter/emitter measured by the downward-sloping curve AEP (which need not be linear). In the business-as-usual or no restriction option, the polluter undertakes x until the private optimal point P where

Figure 1 All-or-nothing vs continuous comparisons.

the net MV equals zero. If this activity x imposes no damages on anyone (and ignoring other problems like ignorance and the second best), this private optimal point is also the social optimal point. However, if it imposes damages on some others or the whole society represented by the marginal damage curve BEC, the social optimal point is where the two curves intersect at E where the level of x is at S. Given the damage imposed, point P is not efficient as the amount of pollution over the range SP yields benefits of only triangle ESP, but results in damages of a much bigger area ESPC. The Pigovian solution is to impose a tax on this external cost on the polluter to shift the marginal value curve from AEP downward to pass through point S, motivating the polluter to reduce the level of x from P to S.

Coase criticized the Pigovian tradition for ignoring the reciprocal nature of the problem and concentrated only on the restriction of the polluters' activity that harms the society. But this restriction affects the polluters. The problem is to avoid the more serious harm. A change of approach is necessary. As Coase did not use either maths or graphical analysis, he compared only the free-to-pollute situation P with the no-pollution situation at the origin (Coase, 1960: p. 41). For such an all-or-nothing comparison, Coase correctly concluded that either of the situations may be more efficient, and a case-by-case examination is necessary. In terms of **Figure 1**, this depends on whether the triangle ABE is larger or smaller than triangle EPC. As a general conclusion is not possible, the presumption against external-cost causing activities or in favor of restricting pollution is not warranted.

Although Coase's conclusion is valid for his all-or-nothing comparison, it is not valid against Pigou. Pigou and his followers did not advocate prohibiting pollution outright or eliminating external costs all together. Rather, Pigou just proposed the imposition of taxes on external costs to reduce their levels toward the social optimal ones, or from point P to point S in terms of **Figure 1**. This is an efficient change as, at the free pollution point P, the net marginal value to the polluter is infinitesimal, while the marginal damage to the sufferers of pollution is large (measured by PC in **Figure 1**). This asymmetry in marginal value was missed by Coase in his all-or-nothing comparison which naturally focuses on the relative size of the two triangles ABE and EPC. Coase was correct only against the extreme environmentalists who want to ban pollution altogether but not against Pigovian tradition which was the main objective of that 1960s paper (which was worth half a Nobel Prize!).

Admittedly, the Pigovian case for taxing pollution should be taken only as prima facie, since administrative and other costs of taxation should also be taken into account, not to mention the danger of letting an inefficient and possibly corrupted government having more excuses to raise revenues and to engage in more corruption. However, even if the environmental scientists' prediction on the likely catastrophic outcomes of the business-as-usual option only has 5% probability of being realized, we certainly should address the problem seriously. Even if a report of a time bomb in your flight has only 1% reliability, you probably want to change your flight!

Even if we agree that taxing pollution and emission of greenhouse gases may be desirable, the appropriate amounts of taxes may be difficult to estimate as the damages are typically on the far future. However, in most cases, it is optimal to tax pollution at least in accordance to the marginal costs of reducing the pollutants, which are easier to estimate. Moreover, it would normally raise sufficient revenue to fund the optimal amount of disruption abatement spending (Ng, 2004b).

We have not covered debates such as the communitarian concern of the negative effects of using the market on altruism or morality (*see* Market and Nonmarket Allocation). Also, over the recent decades, studies by psychologists and behavioral economists have shown that individuals are not perfectly rational with consistent preferences (*see* Behavioral Economics; Experimental Economics). In answer, one approach is to regard a single individual as consisting of a number of 'agents' acting at different times or 'frames.' Without sufficient interagent-comparable cardinal utilities, this leads to very wide indecisiveness (Bernheim and Rangel, 2009; Rubinstein and Salant, 2012; Mandler, 2014). Focusing on experienced utility or actual subjective happiness may be a more fruitful approach (e.g., Kahneman et al., 1997; Kahneman and Sugden, 2005; Ng, 2003; Koszegi and Rabin, 2008), especially if we accept the view that happiness is the ultimate value (Ng, 2013).

Welfare: Philosophical Aspects

Abstract

Given a distinction between 'welfare' and 'utility,' four different ways of thinking about welfare are discussed, namely: hedonistic conceptions, preference conceptions, resource conceptions, and capability conceptions. A laundered preference approach might be a way to combine insights from the different conceptions. If the preferences can always be represented by utility functions, such an approach can take the form of a nondictatorial welfarist philosophy such as standard utilitarianism. This is conceivable if a consensus exists about interpersonal comparisons of utility. But such a consensus cannot reasonably be expected, suggesting the need for a nonwelfarist philosophy. Yet perhaps a nonstandard welfarism may retain appeal, even if preferences cannot always be represented by utility functions and there is no reliance on interpersonal comparisons.

'Welfare' is not an easy term to define with precision. In the abstract, it refers broadly to the happiness, well-being, or good of an individual, society, political association, and so on. More concretely, it also refers to particular ingredients and sources of happiness or good. Life itself is an essential element of any human being's welfare, for example, and the means of basic subsistence, including food and shelter to some minimal extent, can be viewed as vital sources of welfare whose provision should be guaranteed by government, as in the term 'welfare state.' The sources and ingredients of human happiness are so various, however, that 'welfare' in the philosophical sense must not be limited to basic needs or the means of satisfying them. In this article, four different interpretations of welfare are discussed briefly. 'Welfarist' moral philosophies are also contrasted with 'nonwelfarist' moral philosophies. The first step is to dispel some confusion surrounding the term 'utility' and its relationship to welfare.

Welfare and Utility

Modern economists, decision theorists, and game theorists typically distinguish between welfare and utility. Utility in their terminology refers to the value of a mathematical function – strictly speaking, any function in a family of informationally equivalent functions – that *represents* the coherent preferences of a person or of society such that, for any pair of options in the feasible set of outcomes, a larger value is assigned to the preferred option. The relevant family of informationally equivalent utility functions is determined by the given assumptions of measurability and interpersonal comparability of utility. In this regard, measurability must not be confused with comparability across persons. A measurability assumption (such as ordinal measure, cardinal measure, or ratio-scale measure) specifies a particular degree of precision with which any person's preference ranking can be represented by utility numbers – the more precise, the smaller the family of informationally equivalent utility functions. Such an assumption is logically independent of any comparability hypothesis, according to which the utility representations of different persons' preferences are mutually dependent. Given comparability, the utility function which can be used to represent a person's preferences depends on the utility function selected from the family available to represent another person's preferences. In the absence of comparability, however, there is no constraint of this sort on which members of the relevant families can be used to represent the different persons' preferences.

To illustrate, suppose that utility numbers are ordinal and noncomparable. Given the ordinal measure, a person's utility function is unique only up to positive monotonic transformations. Such transformations preserve the order of relative priority of the utility numbers assigned to the alternatives. Given noncomparability, it is permissible to transform any person's utility function without altering the utilities of other people. Thus, a person's ordinal noncomparable utility ranking generally provides no more information than that contained in his own preference *ordering* – a complete, reflexive, and transitive relation – over the alternatives.

If utility numbers are assumed to be cardinal and noncomparable, however, then a person's utility function is unique up to positive linear (strictly speaking, affine) transformations: the cardinal noncomparable family of informationally equivalent functions is more restricted than its ordinal counterpart, which admits positive nonlinear transformations. A cardinal noncomparable utility ranking represents preference information that is richer than his preference ordering, namely, the relative *intensity* with which he prefers one option to another. If his revealed attitudes toward risk are independently assumed to measure how much subjective importance he assigns to his different options, for instance, the Von Neumann–Morgenstern method of cardinalization is appropriate and expected utility functions are valid cardinal noncomparable representations of his preference intensities (see, e.g., Binmore, 1994: pp. 259–278, 304–315).

To take a final illustration, if utility numbers are interpersonally comparable, then one person's utility function cannot be subjected to any transformation unless every other person's utility function is similarly transformed. A cardinal comparable utility ranking provides information not only about the person's preference intensities, for example, but also about how intense his preferences are in comparison to those of other people. To construct such a utility ranking, however, there must

be a method of making interpersonal comparisons apart from a method of cardinalization (Sen, 1979). For instance, a person might extend sympathy to the other members of his society by adopting their personal preference intensities while imagining himself in their respective positions at any pair of alternatives. He must also be able to render the different persons' intensities dimensionally compatible in order to compare them. By reducing them to a common unit, he could form a suitable extended preference reporting that when he places himself in their respective positions, he believes that one person i's preference for x over y is of greater intensity than another person j's preference for y over x, for any two persons and any pair of alternatives. His personal preferences, a subrelation of his extended ones, might continue to be decisive for his actions. But if he can extend sympathy to others in this way, his preferences can be represented by a cardinal comparable utility function. At the same time, different people may disagree with respect to interpersonal comparisons, and thus form conflicting extended preferences. *A fortiori*, different people may have conflicting personal preferences and conflicting cardinal comparable utility functions.

In general, a utility function encapsulates information about measurability and interpersonal comparability of the underlying preferences. As a device for representing this preference information (including orderings, intensities, and interpersonal comparisons), utility in this technical sense is quite distinct from any substantive idea of welfare. Indeed, utility in this sense can conflict with welfare if the preferences being represented are not valid welfare judgments: larger personal utility values can be assigned to outcomes which, though preferred by the agent, are worse in terms of his welfare, for example, just as smaller aggregate utility values can be assigned to outcomes which, though rejected by society, are better in terms of social welfare. Some have argued that the term utility should thus be confined to the technical meaning so as to avoid needless confusion resulting from the identification of utility with 'good' (e.g., Broome, 1991a,b). Perhaps so. But there are reasons to proceed with caution in this. First, utility continues to be associated with welfare – 'being useful or beneficial' – in our everyday language. Even within economics, this everyday association still surfaces occasionally. More confusion may be caused by trying to banish it than by living with it.

Second, the identification of utility with welfare has a long history within both economics and philosophy (Sen, 1987, 1991). Bentham, J. S. Mill, and other classical utilitarian philosophers held that utility means happiness or enjoyment in the sense of pleasure and absence of pain, for example, and that actions ought to be evaluated in terms of their consequences for general happiness or social welfare, maximization of which is the sole ultimate standard of good (*see* Consequentialism (Including Utilitarianism)). For these thinkers, any action or other thing is 'useful' or 'has utility' if and only if it has a tendency to promote pleasure net of pain. They deny (what is commonly asserted) that something may give much pleasure yet be useless, or that something may be useful even though it tends to promote more pain than pleasure. Earlier thinkers such as Hume and Helvetius also may have held this hedonistic idea of utility if not the distinctive utilitarian doctrine that general utility maximization is the *sole* ultimate test of good conduct.

As Mill (1965: pp. 45–46) elaborated the hedonistic idea, three kinds of utilities can be produced by human actions, namely: 'utilities fixed and embodied in outward objects' (such pleasures are created by 'investing external material things with properties which render these serviceable to human beings'); 'utilities fixed and embodied in human beings' (again, such enjoyments are made possible by 'conferring on human beings qualities which render them serviceable to themselves and others'); and, finally, 'utilities not fixed or embodied in any object, but consisting of a mere service rendered; a pleasure given, an inconvenience or a pain averted, during a longer or shorter time, but without leaving a permanent acquisition in the improved qualities of any person or thing; the labor being employed in producing an utility directly, not (as in the two former cases) in fitting some other thing to afford an utility.' Useful material objects and virtuous or noble human beings are *means* to pleasure. After repeated experience of their consequences, however, these more or less permanent sources of pleasure can also become inseparably associated with the idea of happiness itself, through habit, and thus be seen as concrete ingredients of the good (Mill, 1969: pp. 234–239).
